The early Czech Academy also had to manage the symbolic burden of institutional succession. On the one hand, it claimed the legacy of ČSAV and earlier Czech learned institutions, including the Royal Czech Society of Sciences and the Czech Academy of Sciences and Arts (*Czech Academy of Sciences, n.d.*). On the other hand, it had to distance itself from the authoritarian and ideological features of the socialist Academy. This double movement was delicate. Too much emphasis on continuity could make the Academy appear unreformed; too much emphasis on rupture could weaken its historical legitimacy and obscure the genuine scientific achievements of earlier generations. The solution was to construct a layered historical identity: the Academy would acknowledge institutional breaks while presenting Czech science as a longer tradition of learned inquiry, national culture, and international scholarship. Stabilisation therefore had a historical and symbolic dimension as well as a legal one.

One reason the Academy survived the early post-socialist decade was that it did not define itself only as a corporation defending inherited assets. It accepted substantial reductions, introduced evaluation, competed for funding, opened itself to international comparison, and increasingly cooperated with universities and public institutions. These choices did not remove criticism, but they made the Academy's defence more credible. In many post-socialist contexts, academies of sciences were criticised as relics of the Soviet institutional model. The Czech case was different because the Academy could point to internal reform as evidence that it had moved away from the old model while preserving valuable research capacity (*Filáček, 2023*; *Mayntz et al., 1998*). Stabilisation thus depended on the Academy's ability to demonstrate transformation without dissolving itself. Its legitimacy rested on the argument that reform and continuity could be mutually reinforcing.

The first decade also prepared the ground for later legal and organisational reforms. Although the 2005 Act on Public Research Institutions and the 2007 transformation of Academy institutes into public research institutions belong to a later moment, they can be understood as an extension of questions already posed in the 1990s (*Parliament of the Czech Republic, 2005*). Who owns and manages research infrastructure? How should institutes be governed? What is the role of boards, directors, supervisory bodies, and external members? How should research results be reported to the public? How can public research organisations cooperate with universities, state bodies, and enterprises without losing their primary scientific mission? These questions did not appear suddenly in 2005. They emerged from the stabilisation of the 1990s, when the Academy had to convert revolutionary reform into durable institutional design.

The stabilisation of the Academy after 1993 should therefore be seen as a multi-layered process. It involved legal establishment, leadership consolidation, personnel contraction, financial adaptation, internal democratisation, disciplinary reorientation, international reopening, and public legitimation. No single measure guaranteed survival. The Academy stabilised because these elements gradually reinforced one another: law created continuity, evaluation created selectivity, self-government created legitimacy, funding competition created pressure for quality, and international cooperation created external horizons. The process was not smooth, and it should not be romanticised. Careers were disrupted, institutes were abolished, fields were rebalanced, and financial uncertainty became part of academic life. Yet the outcome was not institutional collapse. By the end of the first post-transformation

decade, the Academy had become a smaller but more autonomous and more internationally oriented research organisation.

This transformation also altered the meaning of modernisation itself. In the early 1990s, modernisation could easily have been understood as dismantling the inherited socialist institution and replacing it with a market-compatible research sector. The actual development was more complex. Modernisation meant selective preservation, democratic self-government, quality assessment, plural funding, cooperation with universities, and gradual European integration. It meant building a research institution capable of public responsibility without direct ideological control. It also meant accepting that autonomy would now be defended through performance, credibility, and openness rather than through inherited state privilege. The stabilised Academy was therefore not merely the old ČSAV after reform. It was a new institutional compromise between national scientific continuity and the norms of post-socialist democratic research governance.

Thus, the stabilisation of the Czech Academy of Sciences after institutional restructuring was the foundational phase of its modern history after 1993. The Academy survived because it transformed the traumatic consequences of post-1989 rupture into a new system of legal continuity, internal democracy, selective research quality, and public accountability. Its first decade was marked by financial pressure, personnel losses, disciplinary redefinition, and the difficult abandonment of former privilege, but these pressures also forced the institution to articulate a stronger scientific and civic identity. The Academy became smaller, more competitive, more self-conscious, and more open to international standards. At the same time, it preserved the long-term research capacities without which Czech science would have lost much of its institutional memory. Stabilisation was therefore not the end of transformation, but the condition that made later reforms in funding, evaluation, European integration, open science, and career structures possible.

2. New Funding Conditions and Research Competition

The new funding conditions of the Czech Academy of Sciences after 1993 were among the most consequential elements of its post-transformation history. The Academy did not merely lose the old political framework of the Czechoslovak socialist state; it also entered a radically different economy of public science, in which stable institutional support had to coexist with grant competition, budgetary negotiation, and increasingly formalised evaluation. Under the socialist model, the Academy's institutes had been funded within a centralised state-planning environment, where research priorities, personnel levels, equipment flows, and institutional existence were shaped by political-administrative decisions rather than by open competition. After 1989, this order could no longer be defended either politically or intellectually. Yet the replacement of central allocation by competitive and plural funding did not automatically produce a balanced research system. It created opportunities for initiative, quality selection, and internationalisation, but it also introduced uncertainty, administrative burdens, and unequal pressure across disciplines. The first post-transformation decade therefore forced the Academy to ask a difficult question: how could long-term basic research survive in a funding environment increasingly shaped by short-term projects and public justification?

The legal establishment of the Czech Academy of Sciences preserved a crucial element of financial continuity. The Act on the Czech Academy of Sciences recognised the Academy as a

public institution financed from the state budget and placed it, for budgetary purposes, in a separate chapter of the state budget (*Czech National Council, 1992*). This provision was not a minor technicality. It gave the Academy a direct institutional position in negotiations over public resources and prevented its complete absorption into a ministerial department or university-centred funding model. At the same time, the provision did not guarantee the old scale of support, nor did it protect the Academy from political criticism. Public money had become more openly contested, and the Academy had to justify why a non-university system of research institutes deserved substantial state financing in a democratic and market-oriented Czech Republic. Thus, from the beginning, financial continuity was combined with a demand for legitimation.

The early 1990s were marked by a sharp contraction of the Academy's personnel and resources, and this contraction shaped the meaning of later funding reforms. The radical reduction of staff between 1989 and 1994, discussed in relation to institutional stabilisation, was inseparable from the fiscal environment of transformation (*Filáček, 2023*). The Czech state was reorganising its entire public sector, building new political institutions, liberalising the economy, and redefining the relationship between public expenditure and national priorities. In this context, science could no longer rely on the assumption that inherited institutional structures would automatically be financed. The Academy had to become smaller, more selective, and more accountable. Funding conditions thus reinforced the internal restructuring of institutes. They made scientific quality, public credibility, and capacity for external cooperation not only intellectual values but also survival mechanisms.

The creation of the Grant Agency of the Czech Republic was one of the decisive steps in the formation of the new funding environment. Established in 1993, GA ČR became an independent public organisation supporting basic research across all fields on the basis of calls for proposals (*Czech Science Foundation, n.d.*). Its emergence changed the culture of Czech research because it introduced a national mechanism through which research teams from the Academy, universities, and other institutions could compete for funding according to project quality rather than inherited institutional position. For the Academy, this development was ambivalent. On the one hand, it opened additional resources and allowed strong teams to demonstrate their excellence beyond internal Academy channels. On the other hand, it exposed Academy institutes to direct competition with universities and other research organisations. The Academy's legitimacy increasingly depended not only on its historical role but also on its success in open grant competitions.

Competition for project funding altered the everyday professional behaviour of researchers. Writing proposals, preparing budgets, defining measurable objectives, planning deliverables, and reporting results became increasingly normal parts of scientific work. For researchers trained in the late socialist environment, this was not simply an administrative change. It required a new understanding of research as an activity that had to be narrated, justified, evaluated, and periodically renewed. Scientific ideas now had to be translated into the language of grant applications. Research groups had to learn how to present novelty, feasibility, international relevance, and expected outcomes. The Academy's institutes therefore became sites of cultural adaptation, where scholarly traditions met the managerial vocabulary of projects, calls, deadlines, panels, and evaluation reports.

The introduction of competition had positive consequences that should not be understated. It weakened the automatic reproduction of institutional privilege and created incentives for

methodological innovation, international publication, and younger researchers' initiative. It allowed excellent teams within the Academy to strengthen their position even when their institutes faced budgetary pressure. It also helped establish peer review as a normal instrument of public funding, thereby replacing political discretion with a more professionalised form of judgement. GA ČR's declared mission to support high-quality basic research and international scientific cooperation fitted well with the Academy's own claim to be a leading institution of fundamental research (*Czech Science Foundation, n.d.*). In this sense, competition was not simply an external pressure imposed upon the Academy. It became one of the mechanisms through which the Academy could demonstrate that its institutes were capable of meeting democratic and international standards.

At the same time, competition introduced new inequalities among disciplines and institutes. Research fields with strong publication traditions, relatively clear project cycles, internationally standardised methods, and access to global peer communities could adapt more easily to grant competition. Other fields, especially those dependent on long-term archival work, national collections, scholarly editions, field research, language resources, or cumulative theoretical labour, faced greater difficulty in presenting their work in short project formats. Humanities and some social sciences could participate in grant systems, but the rhythm of their work often differed from the rhythm assumed by funding calls. Long-term dictionaries, critical editions, archaeological documentation, and national historical corpora could not always be reduced to the logic of three-year project outputs. The Academy therefore had to defend the idea that competitive funding should complement, not replace, stable institutional support.

This tension between institutional and targeted funding became one of the most important structural questions of Czech science policy. Institutional funding supported the long-term conceptual development of research organisations, maintained infrastructure, preserved staff continuity, and allowed institutes to pursue strategic directions beyond immediate project cycles. Targeted or project funding, by contrast, supported specific research tasks selected through competition. Both forms were necessary, but they implied different temporalities of science. Institutional funding protected the slow accumulation of knowledge; project funding stimulated initiative and accountability. The difficulty was not the existence of competition itself, but the proportion between stable and competitive resources. If project funding became too dominant, the Academy risked losing the capacity to sustain disciplines whose value depended on continuity.

The Academy attempted to manage this tension through its own internal funding mechanisms. It was among the first Czech institutions to establish an internal Grant Agency, supporting research projects selected through peer review and involving foreign reviewers (*All European Academies, 2015*). This internal mechanism was important because it allowed the Academy to introduce competition without abandoning its responsibility for the development of institutes. It also helped researchers become familiar with peer-review procedures in a comparatively protected institutional environment. Internal grant schemes encouraged initiative among research teams and gave the Academy a tool for identifying emerging excellence. They also demonstrated that the Academy was capable of self-modernisation. Rather than waiting for external reformers to impose competitive principles, it incorporated competition into its own governance culture.

The emergence of grant competition changed the relationship between institutes and the central Academy administration. In the older model, institutes could expect a relatively direct connection between institutional existence and budgetary allocation. In the new model, institutes needed to combine Academy resources, GA ČR grants, ministerial programmes, international projects, contractual research, and later European structural or framework programme funding. This created a more plural financial environment, but also a more complex one. Institute directors increasingly had to act not only as scientific leaders but also as strategic managers of funding portfolios. They had to balance permanent staff, project staff, equipment needs, overheads, and co-financing obligations. The financial life of the Academy thus became less centralised and more project-sensitive, even while the Academy continued to defend institutional support as the foundation of basic research.

The new funding conditions also reshaped relations between the Academy and universities. Grant competition placed Academy institutes and university departments in a more direct field of comparison. This could stimulate cooperation, but it could also produce rivalry, especially in disciplines where research capacity was limited and national funding pools were relatively small. Universities, newly liberated and increasingly research-oriented after 1989, sought to strengthen their role in doctoral education, international publication, and research funding. The Academy, meanwhile, argued that its institutes provided concentration, infrastructure, and long-term expertise that universities alone could not easily sustain. In practice, the most productive outcome was not institutional rivalry but the gradual formation of joint doctoral programmes, shared projects, and collaborative research centres. Funding competition therefore contributed both to differentiation and to cooperation within the Czech research system.

The Academy's adaptation to new funding conditions must also be understood in the context of the broader post-socialist transformation of East European academies. Across the region, academies of sciences had to defend themselves against accusations of bureaucratic inheritance, low efficiency, and isolation from universities (*Mayntz, Schimank, & Weingart, 1998*). Some were drastically weakened; others preserved more of their institutional capacity. The Czech Academy's position was distinctive because it accepted substantial restructuring while maintaining a strong research profile. Funding competition was central to this outcome. It made it possible to argue that Academy institutes were not merely protected remnants of the old system but research performers capable of competing for peer-reviewed support. In this sense, competition became part of the Academy's post-socialist political language.

However, the new system also introduced what may be called the projectification of academic life. Research increasingly had to be divided into projects, each with its own title, budget, timeline, objectives, and expected outputs. This helped clarify goals and make public support more transparent, but it could also fragment intellectual agendas. A scientist might spend substantial time maintaining a chain of grant applications, reports, and renewals rather than concentrating on deeper research questions. Younger researchers learned early that career development depended on project participation and success in competitions. Directors learned that institutes could not rely on institutional funds alone. The Academy's modernisation therefore carried an internal cost: the growth of administrative labour within the scientific profession.

The legal framework of research funding became more explicit with Act No. 130/2002 Coll., which regulated support for research and development from public funds (*Parliament of the*

Czech Republic, 2002). This Act marked the consolidation of principles that had been developing throughout the 1990s: public support should be defined, classified, allocated, recorded, and evaluated within a formal national system. For the Academy, this meant that its financial environment was increasingly connected to nationwide rules of research governance. Funding was no longer only a matter of annual negotiation or institutional tradition. It was part of an expanding legal and administrative architecture, including information systems, public calls, programme rules, and later evaluation methodologies. The Academy's ability to navigate this architecture became a major factor in its institutional strength.

The distinction between basic and applied research also became more visible in the new funding order. The Academy traditionally presented itself as a leading institution of basic research, but many of its institutes also had applied capacities, technological expertise, public-service functions, and links to industry or state administration. GA ČR provided a core mechanism for basic research, while later reforms led to the creation of the Technology Agency of the Czech Republic in 2009 as a major provider for applied research and experimental development (*Technology Agency of the Czech Republic, n.d.*). Although TA ČR belongs to a later phase than the first post-transformation decade, its establishment continued a trajectory that began in the 1990s: the differentiation of funding instruments according to the type and purpose of research. This differentiation mattered for the Academy because it required institutes to define more clearly whether a given activity was basic, applied, infrastructural, strategic, or service-oriented. Funding competition thus pushed the Academy towards sharper self-description.

The problem was that the boundaries between these categories were often porous. Fundamental research can produce long-term technological consequences, while applied problems can generate new theoretical questions. Many Academy institutes worked precisely in this borderland. Materials science, biomedicine, environmental research, informatics, archaeology, and social research all produced knowledge that was at once scholarly and socially useful. Funding systems, however, tend to demand classification. They ask whether an activity belongs to basic research, applied research, innovation, infrastructure, or public service. The Academy therefore had to translate complex research practices into funding categories that did not always capture their full intellectual character. This became one of the permanent tensions of modern research governance.

The growing importance of research evaluation affected funding even before formal national methodologies became dominant. Once public money was allocated through competition, assessment criteria became politically and institutionally consequential. Peer review, bibliometrics, output registers, international panels, and institutional reports gradually became part of the financial life of research organisations. This development would later culminate in more systematic research evaluation mechanisms, but its origins lay in the funding reforms of the 1990s and early 2000s. The Academy had to learn not only how to do research but how to make research visible to evaluators. Visibility was not identical with quality, but it increasingly influenced resources. The new funding order therefore created a relationship between scientific work and the techniques used to count, classify, and judge it.

The risks of excessive quantification became visible in later debates on Czech performance-based research funding. Studies of the Czech system criticised the use of a single performance-based model for highly diverse research organisations and warned against placing institutions with different missions into a common competitive mechanism (*Arnold et*

al., 2011). This criticism was especially relevant to the Academy because its institutes differed not only from universities but also from departmental research organisations, applied research bodies, and industrially oriented institutions. The mission of an institute devoted to medieval studies, high-energy physics, plant genetics, or social transformation could not be evaluated by a single narrow logic. Funding competition was necessary, but competition without mission sensitivity could distort research behaviour. The Academy's later defence of more nuanced evaluation was therefore rooted in the funding pressures that emerged after 1993.

The crisis around the Academy's budget in the late 2000s illustrated how fragile the balance between stability and competition remained. Government proposals for significant cuts to Academy funding provoked strong reactions from the scientific community and led to public protests and negotiations (*Linková, 2015*). Although this episode belongs chronologically after the first post-transformation decade, it revealed the unresolved tension created in the 1990s. If institutional support was reduced too far, Academy institutes would become dependent on short-term grants and lose the capacity for strategic disciplinary development. Linková notes that the share of institutional funding in the Academy's budget declined substantially between 2007 and 2013, while competitive funding became increasingly important in some institutes (*Linková, 2015*). This was not only a financial issue. It concerned the very model of public research: whether the Academy would remain a stable infrastructure of national science or become a loose aggregation of grant-dependent teams.

The transformation of Academy institutes into public research institutions under Act No. 341/2005 Coll. also affected funding conditions. The new legal form strengthened the public institutional identity of research organisations and provided a clearer framework for their governance, property, reporting, and accountability (*Parliament of the Czech Republic, 2005*). This reform helped align the Academy's institutes with a modern legal environment for public research. It also clarified the relationship between institutes, their founder, public resources, and external partners. Financial management became more transparent and more closely connected with institutional strategy. The change did not eliminate funding uncertainty, but it gave institutes a legal form better suited to diversified financing and modern research governance.

European integration added another layer to the funding environment. Before the Czech Republic joined the European Union, Academy institutes had already been rebuilding international contacts and participating in selected European programmes. After accession, European framework programmes, mobility schemes, infrastructure initiatives, and structural funds became increasingly important. These resources offered opportunities that were unimaginable under late socialism, but they also required administrative competence, co-financing, international networking, and project-management capacity. Competition now occurred not only within Czech national science but also within European research space. The Academy's institutes had to compete with well-established Western European universities and research organisations, often from a weaker starting position in terms of infrastructure and salary levels. European funding therefore expanded horizons while intensifying pressure.

The internal effects of funding competition were not uniform. Some Academy institutes became highly successful in national and international grant systems, developing diversified funding portfolios and strong project offices. Others remained more dependent on institutional support because their research profiles did not easily attract large external grants. This diversity was not necessarily a sign of weakness. It reflected the heterogeneity of research

missions within the Academy. A modern academy of sciences contains laboratories, archives, collections, theoretical groups, field research teams, computational centres, and institutes serving public knowledge needs. The challenge was to design funding mechanisms that recognised this diversity without shielding weak performance. The Academy's financial modernisation therefore required a delicate balance between excellence, mission, continuity, and renewal.

Competition also had a generational dimension. Younger researchers could use grants to gain autonomy, build small teams, travel abroad, and establish independent research profiles. In this respect, competitive funding opened spaces that had been far more restricted in hierarchical institutional cultures. However, it also produced new precarity. Early-career researchers could become dependent on short-term contracts, project cycles, and the priorities of principal investigators. The same mechanisms that created opportunity also increased insecurity. For the Academy, this meant that funding reform was not merely a matter of institutional finance; it affected career structures, mentorship, recruitment, and the ability to retain talented researchers. Later debates on early-career researchers, gender, mobility, and leadership cannot be separated from this funding environment.

The administrative burden of competition became more visible as the system matured. Grant applications, financial reports, audits, procurement rules, evaluation documents, and output registrations required professional support. Institutes had to develop administrative capacities that were not peripheral but essential to research performance. The figure of the project manager, research administrator, international officer, and grant specialist became increasingly important. This development was part of the Europeanisation of research governance, but it also changed the internal sociology of the Academy. Scientific success depended more and more on collaboration between researchers and administrative professionals. Funding competition thus produced a new division of labour within the research institution.

The Academy's central leadership had to defend institutional funding not as protectionism, but as a condition of excellence. This distinction was crucial. In a democratic research system, an institution cannot simply demand public money because it has existed for a long time. It must show that stable support enables forms of research that competitive grants alone cannot sustain. The Academy's argument rested on the value of long-term basic research, scientific infrastructure, disciplinary depth, national collections, and expertise available to society and the state. At the same time, the Academy accepted that institutional funding must be connected with evaluation and accountability. Its position therefore developed into a balanced claim: competition is necessary for vitality, but stable institutional support is necessary for strategic science.

The broader Czech research policy environment gradually moved towards more formal evaluation of research organisations. Methodology 2017+ later sought to move beyond purely output-counting approaches by evaluating research organisations in relation to quality, social relevance, viability, strategy, and mission (*European Commission, 2018*). This later development confirmed a lesson already visible in the Academy's experience after 1993. Funding systems must not only reward measurable productivity; they must also understand what different research organisations are for. Institutes of the Academy are not identical to universities, applied research agencies, or industrial research units. Their funding model must reflect their role in fundamental research, long-term expertise, and national scientific

infrastructure. The movement towards more nuanced evaluation therefore represented a partial correction of earlier funding pressures.

The new funding conditions also changed the Academy's public accountability. Under socialism, accountability was formally directed towards the party-state and its ideological priorities. After 1993, accountability became more plural: to the state budget, to grant agencies, to peer reviewers, to international partners, to the public, and to the scientific community. This pluralisation was a major democratic achievement, but it also created competing expectations. A grant agency might ask for project outputs; government might ask for efficiency and innovation; society might ask for relevance; international peers might ask for excellence; institutes might ask for stability. The Academy had to operate within all these expectations without losing its scientific mission. Funding competition therefore became one of the central arenas in which the meaning of autonomy was renegotiated.

The financial transformation of the Academy should not be interpreted as a simple shift from state dependency to market responsiveness. The Academy remained a public research institution, and its strongest justification continued to be the production of public knowledge rather than private profit. What changed was the manner in which public support was allocated, justified, and monitored. The state no longer financed the Academy as part of a closed socialist science apparatus. It financed, evaluated, and negotiated with it as one of the principal actors in a plural research system. Competition did not abolish public responsibility; it reconfigured it. The Academy's task was to ensure that this reconfiguration did not reduce science to short-term measurable output.

By the end of the first post-transformation decade, the Academy had learned to operate in a mixed funding environment. It preserved institutional support, participated in national grant competition, developed internal peer-reviewed funding, and began to prepare for deeper European integration. This did not solve all problems, but it created a functional model for survival and adaptation. The Academy's institutes were increasingly expected to be scientifically productive, financially strategic, internationally visible, and administratively competent. The price of this model was increased pressure and uncertainty. Its benefit was a stronger connection between autonomy and demonstrated quality. The first decade therefore established the funding logic that would shape the Academy's later modernisation.

Thus, the new funding conditions after 1993 transformed the Czech Academy of Sciences from an institution accustomed to planned allocation into a research organisation operating within a plural, competitive, and increasingly evaluative funding system. State budget support remained indispensable, but it was no longer sufficient as a source of legitimacy or development. Grant competition through GA ČR, internal Academy schemes, later legal reforms, European programmes, and performance-oriented policy instruments changed the behaviour of institutes and researchers. These changes stimulated excellence, openness, and initiative, but they also created risks of project fragmentation, administrative overload, short-termism, and disciplinary imbalance. The Academy's central achievement was not that it escaped competition, but that it gradually learned to combine competition with institutional continuity. This balance became one of the defining features of its modernisation and prepared the ground for later debates on research evaluation, international integration, open science, and the human dimension of academic careers.

3. Rebuilding International Partnerships after 1989

The rebuilding of international partnerships after 1989 was one of the most visible and intellectually transformative dimensions of the Czech Academy's post-socialist modernisation. It was not limited to the restoration of foreign travel, the signing of bilateral agreements, or the gradual inclusion of Czech research teams in European programmes. It changed the very meaning of scientific work after the long experience of ideological control, restricted mobility, asymmetric relations within the Soviet bloc, and limited access to global scholarly communication. For the Czechoslovak Academy of Sciences in the final years of state socialism, international cooperation existed, but it was filtered through political loyalty, institutional hierarchy, security considerations, and the geopolitics of the Cold War. After 1989, international cooperation became not only more open but also more demanding. Researchers had to rebuild contacts, recover trust, enter competitive networks, meet external standards, and learn to operate in scientific environments where reputation was earned through publication, collaboration, project success, and peer recognition. The Academy's international reopening therefore belonged to the same historical process as internal democratisation, institutional evaluation, and the redefinition of research quality. It helped transform the Academy from a national research corporation emerging from socialism into a participant in the European and global circulation of knowledge.

The first meaning of internationalisation after 1989 was symbolic liberation. For many scientists, the possibility of travelling freely, corresponding without ideological suspicion, accessing foreign libraries, attending conferences, and inviting colleagues from abroad represented a return to normal scholarly life. This was especially important because Czech science possessed older traditions of European intellectual exchange that had been repeatedly interrupted by occupation, war, Stalinisation, political purges, and normalisation. The democratic transformation did not create international scientific culture from nothing; it reactivated a suppressed historical expectation that Czech scholarship belonged to a broader European republic of learning. The new Czech Academy of Sciences, established as the successor to the Czechoslovak Academy and to earlier learned institutions, could therefore present international reintegration as both modernisation and historical restoration (*Czech Academy of Sciences, n.d.*; *Czech National Council, 1992*). This duality mattered because the Academy needed to distance itself from the closed and politicised structures of the socialist period without severing itself from the deeper history of Czech scientific culture. International partnerships helped make that distinction credible. They showed that the Academy's future was not a return to a pre-socialist past, but a new participation in open scientific communication.

The legal foundation of the new Academy was already framed in international terms. Act No. 283/1992 Coll. stated that the Academy and its institutes could conclude agreements on international cooperation in scientific activities and technological development (*Czech National Council, 1992*). This provision appears brief, but its institutional implications were substantial. It recognised international cooperation as a normal function of the Academy rather than as an exceptional act requiring political permission. It also granted institutes a practical role in building international relations, which was important because real cooperation often began at the level of laboratories, archives, research groups, and individual scholarly networks. The Academy's central bodies could sign agreements, represent the institution, and set strategic priorities, but the vitality of internationalisation depended on the initiative of researchers themselves. The legal order after 1993 therefore supported a

decentralised and plural pattern of international cooperation. This was one of the ways in which the new Academy moved away from the older model of politically supervised international relations.

The rupture of 1989 also changed the geography of scientific partnership. During the socialist period, cooperation with the Soviet Union and other socialist countries had been privileged politically, even when many researchers maintained professional ambitions directed towards Western Europe or North America. After 1989, Czech scientific institutions faced the task of rebalancing their external relations. This did not mean that all contacts with former socialist countries disappeared; in many fields, personal relations, shared data, and regional expertise continued. However, the centre of gravity shifted towards Western Europe, the United States, and international organisations operating according to different standards of peer review, publication, and project coordination. The Academy had to learn how to participate in networks where political membership did not guarantee scientific relevance. This shift was intellectually liberating but also sobering. Czech researchers discovered that openness did not automatically erase disparities in funding, infrastructure, language competence, or international visibility. The rebuilding of partnerships therefore involved both enthusiasm and the difficult experience of unequal reintegration.

The first post-transformation decade was especially important because it converted spontaneous contacts into institutional channels. In the immediate aftermath of 1989, many international relations were personal, moral, and improvisational. Foreign colleagues invited Czech researchers, sent books and equipment, supported visits, and helped restore scholarly communication. Western foundations, universities, academies, and learned societies often treated Central European science as a field of democratic reconstruction. Yet such assistance could not remain purely charitable or symbolic. The Academy needed durable agreements, regular mobility schemes, joint projects, and channels of project funding. The transition from solidarity to structured cooperation was therefore a major stage in international rebuilding. It allowed Czech institutes to move from being recipients of post-socialist support to becoming partners in research agendas. This shift was essential for institutional dignity and for the long-term stabilisation of the Academy.

Bilateral cooperation played a particularly important role in this process. Agreements with foreign academies, research councils, and scientific organisations created predictable frameworks for mobility, joint workshops, research visits, and later project-based cooperation. Such arrangements were valuable because they lowered the barriers to contact at a time when Czech researchers often lacked the resources to sustain international exchange independently. They also enabled institutes to cultivate relations beyond the most visible centres of global science. Bilateral cooperation could support links with neighbouring countries, historically connected scholarly communities, and partners in disciplines where long-term trust mattered more than rapid project turnover. The present system of CAS bilateral cooperation, based on agreements with partner organisations and realised through Mobility Projects and Mobility Plus Projects, preserves this institutional logic in a more developed form (*Czech Academy of Sciences, n.d.*). Its contemporary structure shows how practices that began as post-transformation reconnection became a stable component of Academy governance. In this sense, bilateral cooperation was both a transitional tool and a durable institutional mechanism.

The relationship with Slovakia had a special character within this broader reconstruction. The dissolution of Czechoslovakia at the end of 1992 created two national academies and two state frameworks, but it did not erase shared disciplinary traditions, personal networks, archives, language proximity, or decades of common institutional life. Czech-Slovak scientific cooperation after 1993 therefore involved both internationalisation and the management of a recent institutional separation. It differed from cooperation with distant foreign partners because it emerged from a common academic biography. At the same time, it required new legal, financial, and organisational forms, since what had once been internal Czechoslovak cooperation now had to be organised across state borders. This made Czech-Slovak relations an important example of continuity within rupture. The Academy's ability to maintain close ties with Slovak partners helped soften the institutional consequences of the federal split. It also preserved a Central European research space in which language, archives, fieldwork, and disciplinary memory continued to matter.

Partnerships with Germany and Austria were also central to the Academy's post-1989 orientation. These relations were shaped by geographical proximity, historical entanglement, economic asymmetry, and the strategic importance of reintegrating Czech science into German-speaking and broader Western European networks. German universities, Max Planck institutes, research foundations, and academies offered models of research organisation, evaluation, and international visibility that were highly relevant for Czech reformers. Austrian cooperation had its own importance, especially in regional, environmental, historical, and cross-border contexts. These partnerships were not merely technical; they carried a symbolic dimension connected with Central Europe's redefinition after the Cold War. Czech science was repositioning itself from the eastern side of a divided continent into a renewed Central European and European research area. The Academy's cooperation with German and Austrian partners thus contributed to a broader cultural geography of post-socialist return to Europe.

French-Czech cooperation developed through both institutional and disciplinary channels. The presence of French research traditions in the humanities and social sciences was especially important because these fields had been deeply affected by ideological isolation under state socialism. The later CEFRES Platform, uniting the French Research Centre in Humanities and Social Sciences in Prague, Charles University, the Czech Academy of Sciences, and CNRS, illustrates how bilateral and multilateral arrangements could generate durable institutional forms in the post-transformation period (*Czech Academy of Sciences, n.d.*). Although the platform in its later form belongs to the mature phase of internationalisation, it reflects a deeper pattern established earlier: international cooperation was not only about laboratory science or technological development. It also helped rebuild theoretical pluralism, archival scholarship, historical interpretation, and social-scientific dialogue. For humanities and social sciences, foreign partnerships offered access to debates that had been partially blocked or distorted under Marxist-Leninist supervision. They therefore supported intellectual normalisation in the richest sense of the word.

Cooperation with the United States and the United Kingdom had a different but equally important role. These links often involved advanced laboratory training, postdoctoral mobility, language integration, publication practices, and access to highly competitive research environments. For younger Czech researchers, periods abroad in Anglo-American institutions could transform professional expectations. They learned not only new methods but also new norms of academic presentation, grant writing, peer review, laboratory management, and disciplinary debate. The consequences of such mobility were uneven because not all

researchers could travel, and not all fields benefited equally. Yet the return of internationally trained scientists gradually changed the Academy's internal culture. It strengthened the expectation that research excellence must be judged in relation to international standards rather than only national reputation. This expectation would later become central to evaluation reforms and career development within the Academy.

The rebuilding of international partnerships was closely connected with the restoration of scholarly communication. Access to journals, databases, books, catalogues, instruments, and conferences was not a secondary issue; it was a condition of scientific reintegration. Under late socialism, many institutes suffered from limited access to current literature and modern equipment, even when individual researchers maintained high intellectual standards. After 1989, the Academy had to overcome accumulated informational deficits. International partners helped through donations, exchanges, subscriptions, joint projects, and training. Libraries and information services became part of internationalisation because they enabled researchers to re-enter contemporary debates. In this sense, the rebuilding of partnerships was also the rebuilding of the material infrastructure of knowledge. Scientific freedom without access to information would have remained incomplete.

International partnerships also helped reshape standards of publication. In the socialist period, many valuable works were published domestically or within limited international circuits, and the criteria of publication could be shaped by institutional and ideological considerations. After 1989, the pressure to publish in internationally visible journals and with recognised academic publishers increased. This pressure was especially strong in the natural and life sciences, where global journal systems were already well developed. In the humanities and social sciences, the process was more complex because national languages, local archives, and culturally specific topics retained scholarly importance. Nevertheless, international cooperation encouraged Czech researchers to translate their work, publish in foreign languages, and enter broader disciplinary conversations. This did not eliminate the value of Czech-language scholarship. Rather, it forced the Academy to balance national scholarly responsibility with international visibility.

European research programmes became one of the decisive instruments through which international partnerships were rebuilt and formalised. The Czech Republic's participation in the 5th Framework Programme from 1999 represented an important step in the pre-accession integration of Czech research into the European Union's scientific structures (*European Commission, n.d.*). The Framework Programme was not simply a funding source. It was a training ground in multinational project consortia, administrative coordination, work packages, deliverables, evaluation criteria, and strategic research agendas. For Academy institutes, participation in European programmes required new competencies that differed from traditional bilateral exchange. Researchers had to join or coordinate international teams, negotiate roles, meet reporting standards, and align their expertise with European priorities. This experience prepared the Academy for deeper integration after the Czech Republic joined the European Union in 2004. It also helped shift international cooperation from visits and personal networks towards project-based and programme-driven collaboration.

The move into European programmes exposed Czech research to competitive asymmetries. Western European institutions often possessed stronger administrative support, better equipment, higher salaries, and longer experience with EU projects. Czech teams could contribute serious expertise, but they often had to overcome reputational and infrastructural

disadvantages. This made early participation both valuable and difficult. It trained researchers in European project culture, but it also revealed the structural gap between post-socialist science and long-established Western research systems. The Academy's response could not be passive imitation. It had to build project offices, improve language skills, professionalise management, and support researchers in proposal preparation. Internationalisation therefore generated internal organisational change. It was not an external ornament attached to research; it became a driver of institutional modernisation.

The Technology Centre of the Czech Academy of Sciences, established in 1994, belonged to this new ecosystem of international research support and European project orientation (*European Commission, n.d.*). Its creation reflected the growing need for specialised knowledge about international programmes, technology transfer, innovation policy, and participation in European research structures. Such organisations were important because the Academy's institutes could not rely solely on individual enthusiasm. They needed guidance, information, contacts, and administrative competence. The development of support structures around European cooperation showed that internationalisation was becoming institutionalised. It also indicated that research excellence increasingly depended on the capacity to navigate complex funding and policy environments. In the long run, this would become one of the defining features of Europeanised research governance.

International partnerships also affected the Academy's relation to the Czech state. Scientific cooperation became part of the country's broader post-1989 foreign-policy orientation towards European integration, transatlantic cooperation, and participation in international organisations. The Academy was not a diplomatic institution in the narrow sense, but it contributed to the intellectual infrastructure of Czech external relations. Through conferences, joint projects, expert networks, and scientific representation, it helped present the Czech Republic as a democratic country with serious research capacities. This was especially important in the 1990s, when the new state had to establish its identity in Europe after the peaceful dissolution of Czechoslovakia. Science offered a language of competence, openness, and continuity that complemented political diplomacy. The Academy's international partnerships therefore had civic and representational importance beyond the internal world of research.

The rebuilding of international cooperation also had a generational dimension. Senior researchers often reactivated contacts interrupted by normalisation or developed during limited earlier exchanges. Middle-generation scientists had to reconstruct careers that had been shaped by institutional constraints and delayed mobility. Younger researchers, by contrast, entered scientific life at a moment when foreign fellowships, doctoral stays, postdoctoral positions, and international conferences became increasingly normal. This produced generational tensions but also opportunities for renewal. Younger scientists could acquire skills and networks unavailable to many of their predecessors, while senior scholars provided institutional memory and disciplinary continuity. The Academy's challenge was to transform individual mobility into collective benefit. International experience had to return to institutes as new methods, publications, collaborations, and mentoring practices.

Brain drain was one of the persistent risks of the international opening. The same freedom that allowed Czech researchers to collaborate abroad also allowed them to leave permanently or to build careers outside the Czech system. In the early 1990s, this risk was especially acute because salaries, equipment, and career prospects in Western institutions were often much

better. Some departures represented a loss of talent that the Academy could not easily replace. Yet mobility also produced diaspora networks, return flows, and long-term collaboration. The question was not whether researchers should be prevented from leaving, since such control would have contradicted the democratic meaning of 1989. The question was whether the Academy could create conditions under which international mobility strengthened rather than depleted Czech science. This issue would remain important in later debates on career structures and early-career researchers.

International partnerships contributed to the reform of research quality by introducing external judgement. Foreign reviewers, advisory board members, visiting scientists, and project partners brought perspectives that could not be reduced to internal institutional politics. This was particularly important after the traumatic evaluation and restructuring of the early 1990s. The Academy needed external standards to demonstrate that reform was not merely domestic political adjustment but a movement towards internationally recognisable quality. International peer review also helped reduce the risk of closed academic circles reproducing themselves without sufficient comparison. Over time, foreign evaluation became increasingly important in institute assessments and grant procedures. The Academy's later evaluation culture therefore had roots in the international reopening of the first post-transformation decade.

The humanities and social sciences experienced international rebuilding in a distinctive way. For them, internationalisation was not only a matter of publication metrics or laboratory cooperation. It involved the reopening of theoretical traditions, comparative methods, archival access, intellectual pluralism, and debate about the meaning of national history after communism. Czech historians, philosophers, sociologists, economists, linguists, and literary scholars entered conversations about memory, democracy, civil society, nationalism, European identity, and post-socialist transformation. Foreign partners were sometimes fascinated by Central Europe as a laboratory of democratic change, while Czech scholars had to avoid being reduced to mere providers of local case studies. The best forms of cooperation treated Czech scholarship as an equal contributor to general knowledge. This was an important part of rebuilding academic dignity after ideological isolation.

In the natural and technical sciences, international partnerships were often tied to equipment, infrastructure, and participation in large-scale facilities. Some fields could not develop without access to expensive instruments, international data, or distributed research networks. Physics, chemistry, molecular biology, astronomy, earth sciences, and materials research increasingly depended on cooperation that exceeded the capacity of a single national institution. Academy institutes therefore had to become participants in broader infrastructures and consortia. This demanded technical competence, financial planning, and strategic alignment. It also changed the scale of research imagination. Scientific problems were no longer defined primarily by what could be done within one institute; they were defined by what Czech teams could contribute to international research systems.

Regional cooperation in Central Europe formed another layer of partnership. The Visegrad area, neighbouring academies, and cross-border programmes offered frameworks for cooperation among countries undergoing related but not identical transformations. Such cooperation was useful because post-socialist institutions faced similar problems of funding, evaluation, mobility, and European integration. At the same time, regional cooperation could not replace broader European and global integration. The Academy had to participate in Central European

networks without becoming confined to a regional periphery. The most productive model was one in which regional cooperation served as a bridge to wider international science. It allowed Czech researchers to compare transformation experiences, develop joint projects, and enter European programmes with partners sharing similar institutional histories.

The rebuilding of partnerships also changed the Academy's internal language of success. Under the socialist system, success could be measured by institutional rank, state recognition, plan fulfilment, or ideological compatibility alongside genuine scientific achievement. After 1989, international collaboration became one of the signs that an institute or research team was scientifically alive. Invitations, joint publications, foreign grants, conference roles, and membership in international organisations became markers of credibility. This did not mean that all international activity was automatically valuable. Some cooperation remained ceremonial or superficial, and some partnerships produced little scientific substance. Nevertheless, the general direction was clear: the Academy's reputation increasingly depended on its capacity to be recognised by partners outside the national system. Internationalisation became a practical test of reform.

The Academy's international partnerships also had to negotiate the relationship between national needs and global science. The Academy could not become merely a branch office of European research agendas, nor could it retreat into national self-sufficiency. Its mission required it to advance knowledge at an international level while also considering the needs of Czech society and national culture (*Czech Academy of Sciences, n.d.*). This balance was especially important in fields dealing with Czech language, history, archaeology, environment, social transformation, and public policy. International cooperation could enrich these fields through comparison and method, but their legitimacy also depended on national scholarly responsibility. The Academy therefore had to show that internationalisation did not weaken its public role in the Czech Republic. On the contrary, good international cooperation could deepen the quality of national expertise.

By the end of the first post-transformation decade, the rebuilding of international partnerships had moved beyond the first emotional phase of reopening. The Academy had established legal, organisational, and professional foundations for international cooperation. Its institutes were participating in bilateral exchanges, restoring disciplinary contacts, entering European research programmes, and developing new expectations of mobility and publication. The process remained uneven, and many weaknesses persisted: limited resources, administrative inexperience, salary gaps, infrastructural deficits, and unequal access across disciplines. Yet the direction was irreversible. Internationalisation had become part of the Academy's institutional identity. It was no longer an exception granted to selected researchers; it was increasingly a normal condition of modern research.

The later development of the Academy's international agenda confirms the durability of this transformation. Contemporary CAS bilateral cooperation is organised through partner organisations, Mobility Projects, Mobility Plus Projects, and running calls with academies and research organisations across Europe and beyond (*Czech Academy of Sciences, n.d.*; *Czech Academy of Sciences, n.d.*). The Academy's involvement in the European Research Area, Horizon programmes, open science structures, and international organisations reflects a mature stage of processes that began with the post-1989 reopening. Even newer initiatives, such as support for researchers at risk and cooperation with Ukrainian scientists after the Russian invasion, reveal that international cooperation has acquired an ethical and civic

dimension as well as a scientific one (*Czech Academy of Sciences, 2022*). This does not mean that the Academy has solved all problems of international competitiveness. It means that international partnership has become one of the basic ways in which the Academy understands its public mission, scientific quality, and European responsibility.

Thus, the rebuilding of international partnerships after 1989 was a decisive element in the stabilisation and modernisation of the Czech Academy of Sciences. It restored freedoms that had been restricted under state socialism, but it also created new demands for quality, competitiveness, mobility, language competence, project management, and external evaluation. The Academy's internationalisation developed from personal reconnections and symbolic gestures of solidarity into bilateral agreements, European programme participation, institutional support structures, and long-term scientific networks. It helped the Academy distance itself from the ideological and geopolitical limitations of the socialist period while preserving and renewing older traditions of Czech participation in European scholarship. The process was uneven, and it exposed Czech science to new inequalities, including funding gaps, infrastructural disadvantages, and the risk of brain drain. Yet without this reopening, the Academy could not have become a modern research organisation. International partnerships transformed not only the Academy's external relations, but also its internal standards, career expectations, evaluation culture, and understanding of scientific autonomy.

Evaluation of Research and Institutional Quality

1. The Development of Research Evaluation Mechanisms

The development of research evaluation mechanisms in the Czech Academy of Sciences was one of the deepest institutional changes of the post-1993 period. Evaluation did not emerge as a neutral administrative technique added to an already stable organisation. It grew out of the moral, political, financial, and scientific dilemmas created by the end of state socialism and by the transformation of the Czechoslovak Academy of Sciences into the Czech Academy of Sciences. The Academy had to demonstrate that it was no longer governed by ideological loyalty, bureaucratic inertia, or inherited institutional privilege. It also had to prove that it could preserve high-quality research without the old forms of state protection. Evaluation therefore became a language through which the Academy could speak simultaneously to scientists, government, universities, foreign partners, and the wider public. It was a mechanism of reform, but also a mechanism of survival. In the first post-transformation decade, to evaluate research meant to answer a larger question: which parts of the inherited Academy possessed genuine scientific vitality, and which parts belonged to the political and organisational world that had collapsed in 1989?

The earliest post-socialist evaluations were inseparable from institutional restructuring. Before the Czech Academy of Sciences formally began its existence in 1993, the institutes inherited from the Czechoslovak Academy had already been subjected to reviews that helped determine which units would continue, which would be reorganised, and which would be abolished or transferred. These early evaluations were not yet part of a refined, stable, and

methodologically elaborate system. They were closer to institutional triage under conditions of political rupture and financial pressure. Yet they established a principle that would define the Academy's later development: the future of an institute had to be justified by scientific quality, not merely by administrative continuity. This was a decisive departure from the late socialist model, in which institutional existence was often protected by planning, hierarchy, and political usefulness. The Academy's later evaluation culture therefore began in a moment of crisis, but its long-term significance lay in the normalisation of quality as a criterion of institutional legitimacy (*Filáček, 2023*; *Mayntz, Schimank, & Weingart, 1998*).

The post-1989 context made evaluation both necessary and painful. Many institutes contained serious researchers and internationally valuable work, but they also carried the marks of ideological supervision, personnel compromises, and uneven scientific standards. This was especially visible in those parts of the humanities and social sciences that had been more directly exposed to Marxist-Leninist doctrine, party historiography, planned social analysis, or politically sanctioned interpretations of culture and society. Evaluation in these fields had to distinguish between compromised institutional frameworks and individual scholarly competence. The same problem appeared in another form in the natural and technical sciences, where the issue was often not ideological distortion but outdated equipment, weak international visibility, excessive dependence on planned industry, or insufficient adaptability to new funding conditions. Thus, from the beginning, evaluation had to be sensitive to disciplinary difference. A single bureaucratic measure could not fairly capture the state of archaeology, molecular biology, philosophy, mathematics, physics, sociology, or materials research.

The establishment of the Czech Academy of Sciences by Act No. 283/1992 Coll. gave evaluation a new institutional setting. The Act defined the Academy's governing bodies, its public status, its connection with the state budget, and its responsibility for scientific research through institutes (*Czech National Council, 1992*). It did not reduce the Academy to a ministry-controlled organisation, but it also did not allow it to exist as a closed corporation of scholars without accountability. The Academy Assembly, Academy Council, President, and Council for Sciences together created a governance framework in which internal self-government and public responsibility could coexist. Evaluation gradually became one of the instruments by which this coexistence was managed. It allowed the Academy to defend autonomy while showing that autonomy was accompanied by internal judgement, external comparison, and public accountability. This connection between self-government and evaluation was one of the most important institutional innovations of the 1990s.

The first function of evaluation was to create confidence after rupture. Scientists who had passed through purges, ideological control, and the sudden uncertainty of transformation needed to believe that the future of their institutes would not be decided only by political revenge, personal networks, or short-term fiscal convenience. Government officials and public critics, on the other hand, needed evidence that the Academy was capable of serious self-reform. Evaluation offered a procedure through which difficult decisions could be presented as grounded in scientific judgement. It did not remove conflict, and it certainly did not make all decisions universally accepted. Careers were interrupted, institutes were closed, and research agendas were redirected. Yet evaluation introduced a more legitimate grammar of institutional change. It turned reform from a purely political act into a process that could at least claim to be guided by scholarly criteria.

Over the 1990s, evaluation became more regular and less exceptional. The Academy's own later methodology explicitly states that CAS had organised regular evaluation of its institutes since its creation in 1993 (*Czech Academy of Sciences, 2019*). This continuity is important. It shows that evaluation was not merely a one-time post-revolutionary purge, but became part of the Academy's permanent governance. The meaning of evaluation changed as the institution stabilised. In the early phase, the central question was whether institutes should survive and in what form. Later, the questions became more strategic: how strong were research teams, how internationally visible were their results, how viable were their plans, how coherent were institute profiles, and how should institutional support be differentiated? Evaluation therefore moved from emergency restructuring towards strategic management.

The growth of competitive funding reinforced this development. Once Academy institutes had to combine institutional support with grants from GA ČR, internal Academy schemes, ministerial programmes, and later European sources, evaluation could no longer remain a purely internal matter. Research quality became connected with public funding, grant success, publication visibility, international partnerships, and institutional strategy. The Academy had to demonstrate not only that its institutes were scientifically active, but also that public resources were being allocated in a rational and defensible manner. This logic was strengthened by Act No. 130/2002 Coll., which regulated support for research, experimental development, and innovation from public funds and linked institutional support to evaluation procedures (*Parliament of the Czech Republic, 2002*). Evaluation thus became part of the financial architecture of Czech research. It mediated between public money and scientific autonomy.

The Academy's evaluation mechanisms developed in dialogue with wider changes in Czech research policy. During the 1990s and 2000s, the Czech Republic gradually built a more formal research governance system, including grant agencies, national information systems, performance indicators, and methodologies for assessing research organisations. This process reflected a broader European movement towards accountability, transparency, and evidence-based allocation of public research funding. Yet the Czech case also carried specific post-socialist tensions. Evaluation had to overcome the legacy of ideological judgement without becoming a merely mechanical exercise in counting outputs. It had to stimulate international competitiveness without destroying research fields dependent on long-term national scholarly tasks. It had to support differentiation between strong and weak research without forcing all institutions into the same mould. The Academy's own evaluation experience became one of the laboratories in which these tensions were worked out.

A central feature of the Academy's evaluation culture was the gradual movement towards informed peer review. Purely internal judgement would have risked reproducing local hierarchies and personal networks. Purely quantitative assessment would have risked flattening the diversity of research into numerical indicators detached from disciplinary meaning. Informed peer review offered a middle path. It combined expert judgement with documentary evidence, selected outputs, bibliometric data where appropriate, institute reports, team profiles, and site visits or hearings. This approach recognised that serious evaluation requires interpretation. Numbers can indicate visibility, productivity, or citation patterns, but they cannot by themselves explain intellectual originality, methodological difficulty, national scholarly responsibility, or long-term potential. The Academy's later methodologies would formalise this balance, but the logic emerged gradually from the need to evaluate a diverse institution fairly.

International participation in evaluation became increasingly important. After 1989, the Academy's legitimacy depended heavily on reintegration into European and global science. It was therefore natural that foreign reviewers and international panels became part of evaluation procedures. Their involvement helped reduce the danger of local self-confirmation and exposed institutes to standards beyond the Czech environment. It also strengthened the Academy's claim that its internal reform was not provincial or merely political, but aligned with broader scientific expectations. International evaluators could assess publication practices, collaboration networks, thematic relevance, and institutional strategy in relation to developments in their fields. This did not mean that foreign judgement was infallible. External reviewers could misunderstand local conditions or undervalue nationally oriented scholarship. Nevertheless, international peer review became one of the strongest instruments for connecting Academy evaluation with global scientific quality.

The discipline-specific character of evaluation was another crucial development. The Academy included institutes working in mathematics, physics, chemistry, biology, earth sciences, medicine-related research, humanities, social sciences, law, philosophy, history, linguistics, archaeology, and many other fields. These disciplines differ profoundly in publication rhythms, authorship patterns, citation cultures, infrastructure needs, language practices, and relations to public relevance. A monograph in history, a critical edition in philology, a patent in applied materials research, a high-impact article in molecular biology, and a long-term ecological dataset cannot be assessed by identical criteria. The Academy's later methodology therefore emphasised field-based evaluation and division into panels and commissions that reflected disciplinary specificities (*Czech Academy of Sciences, 2019*). This was not a minor procedural choice. It was a defence of scientific diversity against crude managerial simplification.

The use of bibliometrics developed cautiously within the Academy's evaluation mechanisms. Bibliometric information could be useful, especially in fields where journal publication, citation patterns, and international indexing were well established. It could help evaluators identify publication visibility, collaboration patterns, and relative positioning in international literature. Yet the Academy's methodology treated bibliometric data as complementary background for informed peer review rather than as an automatic substitute for judgement (*Czech Academy of Sciences, 2019*). This distinction was important because Czech research policy had, at various moments, been criticised for excessive dependence on quantitative output systems and performance-based funding calculations. The Academy's more nuanced approach reflected the need to avoid both anti-evaluation traditionalism and metric fetishism. It recognised that indicators are instruments, not verdicts.

The national debate on performance-based research funding gave additional significance to the Academy's evaluation practices. The Czech evaluation system became known for strong reliance on recorded outputs, points, and quantifiable results, especially in earlier versions of national methodology. Critics argued that this encouraged formal productivity, strategic behaviour, and competition among very different research organisations according to insufficiently differentiated criteria (*Good, Vermeulen, Tiefenthaler, & Arnold, 2015*; *Arnold, Mahieu, Horvath, & Malkin, 2011*). Such criticism was especially relevant for the Academy because its institutes had missions different from those of universities, applied research organisations, industrial laboratories, or departmental institutes. The Academy needed evaluation, but not a system that treated all outputs and all institutions as commensurable in

a simplistic way. Its internal evaluations therefore became an argument for more differentiated, mission-sensitive assessment.

The development of evaluation mechanisms was also closely connected with institutional funding. Evaluation results became one of the background documents for differential institutional support of CAS institutes (*Czech Academy of Sciences, 2019*). This created a direct link between scientific judgement and material consequences. Such a link was necessary if evaluation was to matter, but it also made the process more sensitive. Institutes had to trust that evaluation would not become an arbitrary punishment mechanism. Evaluators had to provide information useful for improvement, not merely scores or rankings. Academy leadership had to use results strategically while preserving the stability needed for long-term research. The connection between evaluation and funding therefore intensified the need for procedural clarity, transparency, and field sensitivity.

Evaluation also reshaped the role of institute directors and scientific councils. Directors could no longer function only as administrators of inherited research units. They had to present institutional strategies, explain research profiles, respond to evaluators' comments, manage weaknesses, and use evaluation results in long-term planning. Scientific councils and boards became important mediators between evaluation findings and everyday research life. They helped translate external assessment into recruitment decisions, thematic priorities, publication strategies, infrastructure development, and cooperation with universities. In this sense, evaluation became a practical tool of institute governance. It was not confined to central Academy documents. It entered the ordinary rhythm of institutional self-description and strategic decision-making.

For research teams, evaluation created both pressure and opportunity. Strong teams could use evaluation to gain recognition, defend resources, attract early-career researchers, and strengthen their position inside institutes. Weaker teams could be asked to change direction, merge, improve international publication, or reconsider their viability. This introduced a more dynamic internal structure into Academy institutes. It also changed the social experience of research. Scientists increasingly had to articulate the significance of their work not only to colleagues in their field, but also to institutional evaluators, management bodies, and funding authorities. Evaluation therefore contributed to the professionalisation of academic self-presentation. Research became something to be performed intellectually and documented institutionally.

The humanities and social sciences posed special challenges for evaluation. Their outputs often include monographs, critical editions, dictionaries, translations, archival publications, expert reports, cultural heritage work, public interventions, and nationally significant scholarship in Czech. International journal metrics alone cannot capture these forms of work. At the same time, these disciplines could not be exempt from quality assessment merely because their outputs are diverse. The Academy had to evaluate them in a way that recognised both national scholarly responsibility and international intellectual standards. This required expert panels capable of understanding language, archive-based scholarship, methodological innovation, theoretical contribution, and public relevance. The development of evaluation mechanisms therefore forced the Academy to think seriously about what quality means in different epistemic cultures.

In the natural and life sciences, evaluation often focused more visibly on international publication, laboratory infrastructure, grant success, collaboration, and participation in global

research networks. Yet even here simple metrics were insufficient. A small team working on a difficult experimental problem, a long-term observatory programme, a specialised facility, or a national research infrastructure could have significance that was not immediately reducible to annual publication counts. Evaluation had to consider vitality, sustainability, technical capacity, international positioning, and strategic relevance. This broadened the concept of quality beyond the single article or citation number. It also encouraged institutes to explain how their research environments functioned, how equipment was used, how young researchers were trained, and how collaboration was organised.

The Academy's evaluation mechanisms increasingly incorporated the idea of societal relevance. This was not identical with immediate commercial application. Societal relevance could include contributions to public policy, education, culture, legislation, health, environment, heritage, public debate, and expert knowledge for state institutions. The Academy's later evaluation methodology explicitly included contribution to knowledge and societal relevance among the main aspects of assessment (*Czech Academy of Sciences, 2019*). This reflected a broader shift from science understood only as autonomous discovery towards science understood as publicly responsible knowledge. The change did not abolish the Academy's commitment to basic research. Rather, it required basic research institutions to explain more clearly how long-term knowledge enters society, often indirectly and over extended periods.

The emergence of Strategy AV21 later gave this development a more programmatic form. Although Strategy AV21 belongs mainly to the mature phase of the Academy's modernisation, it built upon the evaluative culture created earlier. Its emphasis on "top research in the public interest" expressed a desire to connect excellence with social responsibility (*Filáček, 2023*). Evaluation mechanisms were necessary for this ambition because public-interest research cannot simply be declared by institutional rhetoric. It must be supported by credible evidence of quality, cooperation, relevance, and strategic capacity. In this sense, the development of evaluation prepared the Academy for a broader redefinition of its public mission. Quality assessment became one of the institutional foundations of responsible science.

The relationship between Academy evaluation and national Methodology 2017+ was especially important. Methodology 2017+ was introduced as a national framework for evaluating research organisations and research, development, and innovation purpose-tied support programmes (*European Commission, 2018*; *Office of the Government of the Czech Republic, 2018*). It sought to move beyond earlier limitations by combining several modules, including quality of selected results, research performance, social relevance, viability, and strategy. The national system also recognised different categories of research organisations, including universities, institutes of the Czech Academy of Sciences, and departmental or industrial research organisations. This segmentation reflected a lesson already visible in the Academy's experience: research organisations with different missions should not be judged as if they were identical. The Academy's previous evaluations influenced the development of this more nuanced national approach (*Czech Academy of Sciences, 2019*).

The 2015–2019 CAS evaluation illustrates the mature stage of this development. It was conducted under Act No. 130/2002 Coll. and was interlinked with Methodology 2017+, while also remaining more detailed and institution-specific than the national framework (*Czech Academy of Sciences, 2021*). The evaluation distinguished between research-oriented institutes and research-infrastructure institutes, used methodological documents and

annexes, relied on coordination mechanisms, and produced final reports for institutes. It also included research reports, bibliometric background, team quality profiles, final reports, and directors' statements. This structure shows how far the Academy had moved from the early emergency evaluations of the 1990s. Evaluation had become a complex institutional procedure combining documentation, peer review, strategic assessment, and public reporting.

The COVID-19 pandemic affected the 2015–2019 evaluation process and demonstrated the practical resilience of the system. The final report notes that the evaluation took place under exceptionally difficult pandemic conditions and required operative changes to the methodology (*Czech Academy of Sciences, 2021*). This detail is more than an administrative footnote. It shows that evaluation had become important enough to be continued even during a major public crisis, but flexible enough to adapt to extraordinary circumstances. The pandemic also highlighted the wider relevance of research institutions, especially in fields connected with health, modelling, social behaviour, public communication, and expert advice. Evaluation under such conditions had to assess not only past outputs, but also institutional vitality in a rapidly changing environment. This confirmed the importance of combining quality judgement with strategic understanding.

Evaluation mechanisms also changed the Academy's relationship with transparency. The publication of evaluation materials, reports, and methodological documents made the assessment of institutes more visible to the public and to the scientific community. This visibility could be uncomfortable, because it exposed strengths and weaknesses that might previously have remained internal. Yet it also strengthened the Academy's claim to public accountability. A publicly funded research institution must be able to explain how it judges itself and how it uses public resources. Transparency did not mean that every judgement would be simple or universally accepted. It meant that procedures, criteria, and outcomes became part of the public record. This was a major difference from the opaque political-administrative control of the socialist period.

The development of evaluation mechanisms also contributed to the Academy's Europeanisation. European research policy increasingly emphasised excellence, impact, open science, integrity, international collaboration, and responsible use of public funds. The Academy's evaluation culture aligned it with these expectations while preserving its own institutional specificities. Participation in European research programmes, international panels, and comparative standards reinforced the view that evaluation is not merely a domestic bureaucratic requirement. It is part of the common language of modern research governance. At the same time, the Academy's experience shows that Europeanisation cannot be reduced to copying external models. Evaluation had to be adapted to Czech institutional history, disciplinary structure, and the Academy's special role as a network of public research institutes.

The development of evaluation mechanisms inevitably produced tensions. Researchers sometimes experienced evaluation as administrative burden, external pressure, or a source of anxiety. Institutes had to devote time and resources to preparing reports, collecting data, selecting outputs, checking bibliometric information, and responding to panels. There was also the risk that evaluation could encourage strategic behaviour: choosing fashionable topics, maximising countable outputs, avoiding risky long-term research, or privileging easily visible results. These risks are not unique to the Czech Academy; they are part of contemporary

research governance across Europe. The Academy's challenge was to ensure that evaluation served research rather than replacing research with performance theatre. The principle of informed peer review was one response to this danger.

At its best, evaluation created opportunities for institutional learning. It allowed institutes to see themselves through external eyes, compare teams, identify weaknesses, strengthen internationalisation, improve doctoral cooperation, and clarify long-term strategies. It also gave Academy leadership a more evidence-based understanding of the whole institution. Without evaluation, decisions about funding, restructuring, recruitment, and strategic initiatives would have depended more heavily on informal reputation or political negotiation. Evaluation made the Academy more legible to itself. This self-knowledge was one of the quiet but essential achievements of post-1993 modernisation. It transformed the Academy from a historically inherited system of institutes into a more reflective organisation capable of analysing its own performance and future.

The development of evaluation mechanisms therefore altered the meaning of scientific autonomy. In the post-1989 context, autonomy first meant liberation from ideological supervision and political command. Over time, however, autonomy came to mean something more demanding: the right of the scientific community to govern itself through credible standards, transparent procedures, international comparison, and responsibility for public resources. The Academy could defend independence from direct political interference precisely because it developed mechanisms of assessment and accountability. Evaluation was therefore not the enemy of autonomy, although badly designed evaluation could certainly threaten it. Properly understood, it was one of the institutional conditions under which autonomy could survive in a democratic state.

Thus, the development of research evaluation mechanisms in the Czech Academy of Sciences was a long movement from post-socialist institutional triage to systematic, field-sensitive, internationally informed, and strategically useful assessment. Its origins lay in the urgent need to distinguish scientific vitality from ideological inheritance after 1989. Its consolidation was shaped by the Academy's legal status, competitive funding, national research policy, international reintegration, and the growing demand for public accountability. Over time, evaluation became more than a procedure for judging institutes; it became a mechanism for governing the relationship between autonomy, quality, funding, strategy, and public responsibility. The Academy's experience also showed the dangers of crude quantification and the need to combine indicators with expert judgement. By the 2010s and 2020s, CAS evaluation had become one of the most developed instruments of institutional modernisation in Czech science, linking the Academy's historical mission with the contemporary standards of European research governance.

2. Quantitative Indicators, Peer Review, and Institutional Assessment

The relationship between quantitative indicators, peer review, and institutional assessment became one of the most sensitive questions in the modern history of the Czech Academy of Sciences. After the turbulent restructuring of the early 1990s, the Academy increasingly needed evaluation procedures that could be seen as credible, transparent, and methodologically defensible. Yet credibility could not be achieved simply by counting publications, citations, grants, or patents. Nor could it be achieved by relying only on traditional

peer judgement, which might reproduce disciplinary hierarchies, personal networks, or inherited reputations. The central challenge was to combine evidence and interpretation in such a way that evaluation would support research quality rather than distort it. This challenge was especially acute in the Academy because its institutes differed greatly in discipline, mission, publication culture, infrastructure needs, and relationship to public relevance. A common system of assessment had to respect the diversity of mathematics, physics, molecular biology, environmental sciences, archaeology, philosophy, history, linguistics, economics, law, and social research. The Academy's modern evaluation culture therefore developed around a central tension: how to make scientific work visible and comparable without reducing it to a crude numerical hierarchy. This tension placed the Academy within a wider European debate about research assessment, but it also reflected the specific post-socialist history of Czech science.

Quantitative indicators entered Czech research governance with considerable force because they promised objectivity, transparency, and depersonalisation. After decades in which political loyalty and administrative position had often influenced scientific careers and institutional resources, the appeal of measurable outputs was understandable. Numbers seemed to offer a way to replace opaque judgement with visible evidence. Publication counts, citation indicators, journal rankings, grant income, doctoral completions, patents, and other measurable outputs could be recorded, compared, and audited. They offered government and funding bodies a language of accountability. They also helped research organisations show that public money produced identifiable results. In this sense, quantitative indicators were not merely bureaucratic inventions imposed on scientists from outside. They responded to a genuine need for public justification in a democratic research system. The problem was that the same instruments that could increase transparency could also simplify, distort, and over-govern scientific life.

The Czech debate about performance-based research funding revealed these dangers particularly sharply. Earlier national evaluation systems placed substantial emphasis on recorded outputs and point-based calculations, which were intended to allocate institutional funding more fairly and stimulate productivity. However, such systems were later criticised for instability, unpredictability, and insufficient sensitivity to disciplinary and institutional differences (*Good, Vermeulen, Tiefenthaler, & Arnold, 2015*). A method designed to depersonalise and depoliticise funding could, paradoxically, create new incentives for formal productivity rather than genuine excellence. Researchers and institutions might adapt strategically to the scoring system by maximising countable outputs, choosing publication channels for points, or privileging short-term measurable results. This did not mean that indicators were useless. It meant that indicators became dangerous when they were treated as substitutes for scholarly judgement. The Academy's own evaluation culture can be understood partly as a response to this problem.

The Academy's position was distinctive because it had to defend both accountability and disciplinary depth. It could not reject evaluation, since its legitimacy after 1993 depended on showing that public support was linked to research quality. Yet it also could not accept a purely mechanical assessment model without damaging its own institutional mission. Many Academy institutes maintained long-term programmes that do not produce immediate, easily countable outputs every year. Some worked with collections, archives, observatories, dictionaries, long-term ecological data, national language resources, or infrastructure that supports research beyond a single publication cycle. Others produced internationally

competitive articles in fields where bibliometric indicators were meaningful. Still others combined scholarly, cultural, public-policy, and expert functions. The Academy therefore required a model of evaluation capable of seeing both measurable performance and institutional mission. This requirement explains why informed peer review became so central to CAS assessment.

Informed peer review is not a rejection of quantitative evidence. It is a disciplined attempt to place such evidence within expert interpretation. In the Academy's evaluation methodology for 2015–2019, the assessment of research-oriented institutes combined peer review of selected outputs, bibliometrics, institute and team reports, quality profiles, and other documentary materials (*Czech Academy of Sciences, 2019*). This combination recognised that research quality cannot be grasped through a single instrument. Selected outputs allow researchers to present their most significant work; bibliometrics provide contextual information about visibility and citation impact where relevant; reports explain strategy, staffing, funding, infrastructure, doctoral training, and social relevance; expert panels interpret these materials in relation to disciplinary standards. The value of this model lies precisely in the interaction among different forms of evidence. Peer review without evidence can become impressionistic. Indicators without peer review can become blind. Institutional assessment needs both, but it must organise their relationship carefully.

The use of selected outputs was especially important because it shifted attention from mere quantity to quality. A system based only on counting all outputs may reward volume rather than intellectual significance. By contrast, asking institutes or research teams to submit selected results invites them to identify work they consider most important. This creates a different evaluative conversation. The question is not simply how much was produced, but why particular works matter. A selected article, monograph, dataset, patent, edition, software tool, or policy study can be assessed in relation to originality, methodological rigour, international contribution, or societal relevance. Such selection also requires institutional self-knowledge. Research teams must understand their own strongest achievements and be able to explain them to expert reviewers. Evaluation therefore becomes a process of institutional reflection as well as external judgement.

Bibliometric indicators nevertheless retained an important place in fields where they could provide meaningful background. In many natural, medical, technical, and mathematical sciences, publication in international journals and citation patterns are part of the normal communication structure of the discipline. Bibliometric data can help identify whether a research team publishes in visible journals, participates in international debates, and receives attention from other researchers. It can also reveal collaboration patterns and changes over time. However, even in these fields, bibliometrics require caution. Citation practices vary by discipline, subfield, language, team size, and publication type. A highly specialised field may produce lower citation numbers than a fashionable field, even when the work is excellent. An interdisciplinary result may be difficult to classify within conventional categories. A young team may not yet have accumulated citation impact, while an older established team may benefit from accumulated visibility. Bibliometrics must therefore be read, not worshipped.

In the humanities and social sciences, the limits of bibliometric evaluation become even clearer. Major scholarly contributions may appear as monographs, edited volumes, critical editions, dictionaries, translations, archival publications, databases, legal commentaries, expert reports, or culturally significant works in Czech. These outputs often have intellectual

value that international citation databases capture poorly or not at all. National language scholarship may be essential for the development of Czech public culture, education, law, memory, and heritage. At the same time, humanities and social sciences cannot be exempt from standards of quality. They must be evaluated by experts capable of understanding theoretical contribution, archival depth, methodological innovation, interpretive originality, and international relevance. The Academy's institutional diversity therefore makes a strong argument for field-sensitive evaluation. A fair system cannot impose the publication culture of molecular biology on medieval studies, nor can it allow national specificity to become an excuse for weak scholarship.

The Czech Academy's evaluation system tried to address this diversity through panels and commissions structured around disciplinary areas. Such organisation recognised that meaningful assessment requires evaluators who understand the epistemic culture of the field. A panel evaluating an institute of philosophy must ask different questions from one evaluating an institute of physics or microbiology. The relevant outputs, rhythms of work, forms of collaboration, and signs of originality are not the same. Yet disciplinary specificity does not mean disciplinary isolation. Evaluation panels also help compare institutes and teams with international standards within their own fields. They can ask whether a history institute participates in leading historiographical debates, whether a biological institute contributes to internationally recognised experimental research, or whether a technical institute has an appropriate balance between fundamental and applied work. Field-sensitive peer review thus combines respect for difference with an expectation of excellence.

Institutional assessment goes beyond the evaluation of individual outputs. It asks whether an institute is intellectually coherent, strategically viable, well governed, internationally connected, and capable of sustaining future research. This broader perspective is essential for the Academy because its institutes are not merely collections of individual scholars. They are public research organisations with directors, scientific boards, budgets, infrastructure, career structures, doctoral cooperation, administrative systems, and long-term responsibilities. An institute may contain excellent individuals but still suffer from weak strategy, poor mentoring, fragmented teams, or inadequate governance. Conversely, a strategically strong institute may be building emerging capacities whose full results will appear only later. Institutional assessment therefore evaluates research environments as well as outputs. It asks whether the conditions for quality are being created and maintained. This is one of the major differences between mature evaluation and simple output counting.

The assessment of research teams within institutes added another layer of precision. The Academy's 2015–2019 evaluation included reports and quality profiles at the level of research teams, allowing evaluators to see internal variation within institutes (*Czech Academy of Sciences, 2021*). This mattered because institutes are rarely homogeneous. A single institute may contain internationally leading teams, stable mid-level groups, emerging young laboratories, and weaker units that need restructuring. Evaluating only the institute as a whole can hide such differences. Team-level assessment gives directors and Academy leadership more useful information for strategic decisions. It can support stronger teams, encourage mergers, redirect resources, or identify areas needing renewal. It also makes evaluation more directly relevant to the internal governance of institutes. In this sense, institutional assessment became a managerial and developmental tool, not merely an external judgement.

The connection between evaluation and institutional funding gave these assessments practical importance. Evaluation results were intended to provide background for differential institutional support of CAS institutes (*Czech Academy of Sciences, 2019*). This connection made evaluation consequential, but also more delicate. If results influence resources, institutes have strong reasons to care about methods, criteria, reviewer competence, and procedural fairness. A poorly designed system can damage trust, encourage defensive behaviour, and reward superficial adaptation. A well-designed system can help align resources with quality and strategic need. The Academy's challenge was therefore to ensure that assessment did not become a punitive ritual. It had to provide information for improvement, not only justification for budgetary redistribution. This distinction is crucial because research organisations need stability as well as incentives.

Peer review itself is not free from problems. Reviewers bring expertise, but also preferences, disciplinary assumptions, and sometimes bias. They may favour familiar approaches, undervalue risky work, or misunderstand the local mission of a research institute. International reviewers can strengthen objectivity, but they may also lack knowledge of Czech scholarly responsibilities, language-specific outputs, or the historical role of certain institutes. Domestic reviewers may understand the context better, but they may be too close to local networks. Evaluation therefore requires careful reviewer selection, conflict-of-interest rules, balanced panels, clear documentation, and transparent procedures. The Academy's reliance on informed peer review should not be romanticised as pure scholarly wisdom. It is a governance technology that must itself be governed.

The same caution applies to quantitative indicators. Indicators can discipline rhetoric by requiring evidence, but they can also produce artificial certainty. Publication counts may show activity but not depth. Citation impact may indicate visibility but not necessarily originality or social value. Grant income may show competitiveness but can favour fields with more funding opportunities. Patent numbers may indicate applied potential but not the quality of basic science. Doctoral numbers may reveal training activity but not necessarily mentoring quality. International co-authorship may signal cooperation but not always intellectual substance. Every indicator answers only a limited question. The Academy's evaluation culture therefore had to resist the temptation to turn partial signals into complete judgements.

One of the most damaging effects of excessive metricisation is strategic behavioural adaptation. When researchers know that particular outputs or indicators are rewarded, they may reshape their work to fit the assessment system. This can stimulate productivity, but it can also produce salami-slicing of publications, avoidance of difficult long-term questions, neglect of national scholarly tasks, preference for fashionable topics, or overproduction of low-value outputs. Institutions may invest more in improving measurable performance than in strengthening intellectual quality. Such behaviour is not a moral failure of individual researchers; it is a predictable response to incentive structures. The criticism of the Czech performance-based research funding system was precisely that it risked encouraging such distortions (*Good et al., 2015*). The Academy's more balanced assessment model therefore served as a corrective against an overly mechanical output economy.

At the same time, the Academy could not retreat into an anti-metric culture. In modern research governance, public institutions must provide evidence of performance. Government, taxpayers, international partners, and the scientific community have legitimate reasons to ask what publicly funded institutes produce. Without data, evaluation becomes opaque and

vulnerable to informal power. The question is not whether indicators should exist, but how they should be used. Indicators are useful when they support expert judgement, reveal patterns, raise questions, and identify areas for closer analysis. They become harmful when they claim to settle questions that require interpretation. The Academy's methodological development therefore represented an attempt to civilise indicators by embedding them within peer review and institutional analysis.

The national Methodology 2017+ expressed a similar move towards a more complex model of assessment. It divided evaluation into modules, including peer review of selected results, bibliometric analysis, social relevance, viability, and strategy (*Office of the Government of the Czech Republic, 2018*). This modular structure recognised that research organisations cannot be evaluated only by one dimension of performance. The first two modules address results and bibliometric context, while later modules ask broader questions about institutional environment, social contribution, and strategic development. The Academy's experience influenced this national shift, since the evaluation of CAS institutes provided an important precedent for combining international peer review, bibliometrics, and institutional assessment. Methodology 2017+ therefore can be seen not only as a national policy reform but also as a partial generalisation of lessons already learned within the Academy. It represented a movement away from simplified counting towards more differentiated judgement.

The distinction between national evaluation and Academy-specific evaluation is important. National methodologies must cover a wide variety of research organisations, including universities, Academy institutes, departmental institutes, and other public or private research bodies. They therefore require a degree of generality. Academy evaluation, by contrast, can be more closely adapted to the specific structure and mission of CAS institutes. This allows for more detailed institute reports, team-level assessments, and direct institutional learning. The Academy's evaluation can ask questions that are especially relevant to its own governance: how should institutional support be differentiated among institutes; which teams need strengthening; which areas require renewal; how do institutes contribute to Strategy AV21; how do they cooperate with universities; how do they sustain research infrastructures? This specificity is one reason why Academy evaluation remained important even within the broader national system.

Institutional assessment also included attention to management and governance. Scientific quality is not produced only by brilliant individuals; it is shaped by leadership, recruitment, infrastructure, internal communication, doctoral training, administrative capacity, and strategic coherence. An institute with weak governance may fail to support promising researchers or may allow declining teams to persist without renewal. An institute with strong governance can create conditions for excellence, international collaboration, and generational change. Evaluation therefore had to examine not only past publications but also institutional vitality. This was especially important in a post-transformation academy where leadership structures had already been rebuilt after 1989 and where directors increasingly had to operate as strategic managers. Assessment of governance linked scientific evaluation with the broader modernisation of research organisations.

The question of grants and external funding formed another part of institutional assessment. Success in competitive funding can indicate the ability of research teams to formulate strong projects and gain peer recognition. It also helps institutes diversify resources and participate in national or international networks. However, grant income cannot be used as a simple proxy

for quality. Some fields have more grant opportunities than others; some socially or nationally important work is less likely to attract large project funding; some excellent basic research may require long periods before becoming competitive in external calls. Evaluation therefore had to interpret grant success in context. For Academy institutes, the right question was not only how much external funding had been obtained, but whether the funding portfolio supported a coherent and sustainable research strategy.

Doctoral training and cooperation with universities became increasingly relevant in evaluation. Although the Academy is not a university, its institutes play an important role in doctoral education through cooperation with universities, supervision, laboratory training, archival work, and research projects. Institutional assessment therefore had to consider how institutes contribute to the formation of new researchers. This is not a secondary issue. The future of the Academy depends on its ability to attract, train, mentor, and retain younger generations. Evaluation of doctoral involvement, supervision success, and participation of students in outputs helps reveal whether institutes are living research environments or ageing structures sustained by past reputation. In this respect, evaluation connects research quality with the human dimension of institutional modernisation.

Internationalisation also entered institutional assessment as a sign of scientific vitality. Evaluation considered international collaboration, mobility, co-authorship, participation in projects, foreign grants, and the presence of researchers in international networks. Such indicators and peer judgements helped determine whether institutes were active participants in global or European science. However, internationalisation too had to be interpreted carefully. A large number of international contacts does not automatically mean deep cooperation, and a nationally oriented field may have fewer foreign co-authored publications while still maintaining high scholarly quality. The strongest evaluations looked not only at the existence of international links but at their intellectual substance. Did cooperation lead to significant outputs, methodological renewal, access to infrastructure, or training opportunities? This question connected internationalisation with quality rather than treating it as a decorative statistic.

Societal relevance complicated the relationship between quantitative indicators and peer review still further. Some contributions to society can be counted: expert reports, patents, policy documents, public lectures, media outputs, exhibitions, databases, or applied contracts. Yet the deeper social value of research often resists immediate measurement. A historical interpretation may change public memory slowly; an ecological dataset may become crucial years later; a linguistic resource may support education, translation, and cultural identity; basic biological research may have medical implications only after a long period. The Academy's evaluation therefore had to avoid reducing societal relevance to instant impact. It needed expert judgement capable of recognising indirect, delayed, and culturally embedded forms of public value. This was especially important for an Academy whose mission includes both fundamental research and expertise for society.

The assessment of research infrastructures formed another important dimension. Some CAS institutes maintain facilities, instruments, collections, databases, observatories, or archives that support wider research communities. Their value may not be visible through the ordinary output profile of a research team. Infrastructure may enable other researchers' publications, preserve long-term data, or provide national capacity in specialised areas. Evaluating such institutes requires attention to service quality, accessibility, sustainability, technical

competence, and strategic importance. The Academy's distinction between research-oriented institutes and research-infrastructure institutes acknowledged this issue. It showed that institutional assessment must adapt to organisational function. A research infrastructure cannot be evaluated exactly like a small theoretical group, even though both belong to the same Academy.

Evaluation also had a temporal dimension. Quantitative indicators often look backwards, recording outputs already produced. Peer review can also be retrospective, but institutional assessment must include the future. An institute may have excellent past performance but weak renewal capacity. Another may be younger, less visible, but strategically promising. Evaluation therefore had to ask about plans, recruitment, emerging fields, succession, infrastructure development, and long-term viability. This prospective dimension is essential for institutional governance. A public research organisation must not only reward past achievements; it must shape future capacity. In the Academy, this meant that evaluation could become an instrument of renewal rather than simply a record of accomplishment.

The presence of directors' statements in evaluation packages was important because it allowed institutes to respond to final reports. Evaluation should not be a one-way verdict issued by panels to passive institutions. It should create dialogue. Directors can clarify misunderstandings, comment on recommendations, explain constraints, and outline how the institute intends to respond. Such responses do not cancel the authority of evaluators, but they make evaluation more reflexive and institutionally useful. They also strengthen the accountability of institute leadership. Once an institute has publicly responded to evaluation findings, it becomes easier to follow whether recommendations are taken seriously. This transforms assessment into part of an ongoing governance cycle.

The publication of evaluation materials increased transparency. CAS makes general documents and institute-level evaluation materials available, including methodology, reports, selected documentation, and final assessment materials (*Czech Academy of Sciences, 2021*). This openness matters because the Academy is funded from public resources and claims a special role in national science. Public evaluation documents allow other researchers, policymakers, journalists, and citizens to see how institutes are assessed. They also make the Academy's internal standards visible. Transparency can create discomfort, especially when weaknesses are identified, but it strengthens institutional credibility. It shows that evaluation is not a secret administrative act. It is part of the public responsibility of a modern research organisation.

The interaction of indicators and peer review also changed the internal culture of institutes. Researchers became more aware of publication strategy, journal visibility, citation patterns, grant competitiveness, international collaboration, and documentation of outputs. This awareness could improve research planning, but it could also create anxiety and administrative fatigue. Scientists increasingly had to spend time explaining, recording, and framing their work. The modern Academy therefore became not only a place of research but also a place of continuous self-observation. This is a general feature of contemporary research institutions. The challenge is to ensure that self-observation supports scholarly work rather than consuming it. Evaluation must provide feedback without turning the institute into a permanent reporting machine.

Institutional assessment also influenced career structures. Teams and institutes with strong evaluations could attract researchers, support promotions, justify new positions, and

strengthen grant applications. Weak evaluations could lead to restructuring, reduced support, or pressure on leadership. Evaluation therefore entered the biography of researchers indirectly through the reputation and resources of their institutes. For early-career researchers, this could be beneficial if evaluation strengthened dynamic teams and improved mentoring. It could also be risky if institutional pressure produced short-termism, precarious contracts, or excessive focus on measurable outputs. The human dimension of evaluation is therefore unavoidable. Assessment systems do not judge abstract institutions; they affect real careers, identities, and intellectual choices.

The Academy's experience shows that the opposition between indicators and peer review is too simple. The real issue is not whether one should choose numbers or judgement, but how different forms of evidence are combined. Quantitative indicators can reveal patterns invisible to individual reviewers. Peer review can interpret meaning invisible to indicators. Institutional assessment can connect both to governance, strategy, and public mission. The quality of evaluation depends on the architecture of this combination. If indicators dominate, evaluation becomes mechanical. If peer review is unsupported by evidence, it becomes vulnerable to subjectivity. If institutional assessment is absent, neither indicators nor peer review can tell whether an institute is viable. The Academy's mature model therefore rests on triangulation rather than methodological purity.

This triangulated model also reflects the Academy's post-socialist institutional memory. After 1989, the Academy had to escape both ideological judgement and bureaucratic inertia. Quantitative indicators promised a route away from personal and political arbitrariness, while peer review promised a route back to scholarly authority. Institutional assessment promised a way to connect both with public accountability. The difficulty was that each solution contained its own risk. Indicators could become a new bureaucracy; peer review could become a new closed circle; institutional assessment could become managerial control. The Academy's evaluation culture developed by trying to balance these dangers. Its history therefore illustrates a broader lesson of democratic research governance: no evaluation instrument is innocent, and every instrument must be embedded in procedures that limit its misuse.

By the 2010s and early 2020s, the Academy's evaluation mechanisms had become more sophisticated than the simple performance-based systems that had attracted criticism in Czech research policy. They incorporated selected outputs, bibliometric background, expert panels, team reports, institute strategies, social relevance, infrastructure, governance, and future development. This did not eliminate all tensions. Researchers still faced pressure, institutes still had to prepare extensive documentation, and disagreements over quality remained inevitable. Yet the system represented a significant institutional achievement. It allowed the Academy to make differentiated judgements about a highly diverse set of institutes without abandoning either evidence or expertise. It also connected evaluation with the strategic management of public research. In this sense, evaluation became one of the central instruments through which the Academy modernised itself after the initial post-transformation decade.

Thus, the relationship between quantitative indicators, peer review, and institutional assessment in the Czech Academy of Sciences reveals the complexity of modern research governance. Indicators brought transparency, comparability, and accountability, but they also carried risks of simplification, strategic behaviour, and disciplinary injustice. Peer review brought expert interpretation and sensitivity to intellectual quality, but it required safeguards

against bias, localism, and subjectivity. Institutional assessment connected outputs and expert judgement with governance, strategy, infrastructure, social relevance, and future viability. The Academy's mature evaluation model sought to combine these elements through informed peer review rather than reduce quality to a single number. This balance was essential for an institution whose mission includes both internationally competitive research and long-term national scholarly responsibility. The development of this evaluative architecture therefore marked a major stage in the Academy's transformation from a post-socialist successor institution into a modern, accountable, and strategically self-aware research organisation.

3. The Reform of Research Evaluation in the 2020s

The reform of research evaluation in the 2020s marked a new stage in the modernisation of the Czech Academy of Sciences. It did not abolish the evaluative culture that had developed since 1993, nor did it reject the need for accountability in a publicly funded research institution. Rather, it sought to correct the distortions produced by excessively mechanical assessment, to deepen the role of qualitative judgement, and to place the Academy within a broader European movement for responsible research assessment. The issue was no longer simply whether research should be evaluated. That question had already been answered by three decades of post-socialist institutional development. The more difficult question was how evaluation should be conducted so that it would strengthen science rather than narrow it. In this sense, the 2020s reform was not a technical adjustment, but an intellectual and institutional reorientation. It asked what kind of scientific culture the Academy wanted to cultivate: one governed by proxy indicators and defensive reporting, or one capable of recognising quality, originality, public responsibility, disciplinary diversity, and long-term contribution.

The background to this reform lay in the accumulated experience of Czech research evaluation since the 1990s. Early post-transformation evaluation had helped the Academy distinguish viable research capacity from ideological inheritance and organisational inertia. Later systems connected evaluation with institutional funding, grant competition, national research policy, and public accountability. By the 2000s and 2010s, however, Czech science had also experienced the limitations of output-counting and performance-based funding systems. The criticism of the earlier Czech model was not that evaluation existed, but that it often reduced research quality to formalised result categories, points, database entries, and metrics detached from disciplinary meaning (*Good, Vermeulen, Tiefenthaler, & Arnold, 2015*; *Arnold, Mahieu, Horvath, & Malkin, 2011*). The reform of the 2020s therefore emerged from a double lesson. Evaluation was necessary for democratic accountability, but evaluation could become damaging if the instruments used to measure science began to reshape science in their own image.

Methodology 2017+ represented a major step away from the most reductionist features of the earlier national system. It introduced a modular approach to the assessment of research organisations and research, development, and innovation support programmes, combining the evaluation of selected results, research performance, societal relevance, viability, strategy, and governance (*Office of the Government of the Czech Republic, 2018*). This modular structure was important because it acknowledged that research organisations are complex institutions, not mere output machines. It also recognised that different forms of evidence are

needed to evaluate different dimensions of research quality. A selected scholarly output must be assessed differently from an institute's long-term strategy, and both differ from societal relevance or organisational governance. The Methodology therefore reflected a broader shift in Czech research policy from a narrow performance-counting model towards a more differentiated and mission-sensitive framework.

For the Czech Academy of Sciences, Methodology 2017+ had particular importance because it recognised the specific position of Academy institutes within the national research system. Universities, Academy institutes, departmental research organisations, and industrial research bodies do not have identical missions, even when they all produce research outputs. The Academy's institutes are public research organisations with strong responsibilities for basic research, national scholarly infrastructure, long-term expertise, international cooperation, and, in some cases, public-service functions. A uniform evaluation model that treated them as if they were universities or applied research agencies would be methodologically weak and institutionally unjust. The reform of research evaluation in the 2020s therefore strengthened the argument that assessment must be linked to institutional mission. In the Academy's case, this meant evaluating not only productivity but also scientific depth, strategic coherence, disciplinary responsibility, infrastructure, and contribution to society.

The 2020s also placed Czech research evaluation within a wider European debate on responsible assessment. Across Europe, universities, academies, funders, and research organisations increasingly questioned the inappropriate use of journal impact factors, h-indexes, rankings, and other proxy metrics. The San Francisco Declaration on Research Assessment had already argued that journal-based metrics should not be used as surrogate measures of the quality of individual research articles, researchers, or institutional contributions (*DORA, 2013*). The Leiden Manifesto similarly formulated principles for responsible metrics, emphasising the need to support qualitative expert assessment, account for disciplinary variation, protect locally relevant research, and avoid misplaced precision (*Hicks, Wouters, Waltman, de Rijcke, & Rafols, 2015*). The Metric Tide report in the United Kingdom also warned against metric misuse and advocated responsible metrics based on robustness, humility, transparency, diversity, and reflexivity (*Wilsdon et al., 2015*). The Academy's reform therefore did not occur in isolation. It was part of a broader attempt to rethink how modern science should be judged.

The Coalition for Advancing Research Assessment gave this European discussion a more organised institutional form. The Agreement on Reforming Research Assessment formulated a vision in which assessment should recognise diverse research outputs, practices, and activities, while relying primarily on qualitative judgement supported by responsible use of quantitative indicators (*Coalition for Advancing Research Assessment, 2022*). The Czech Academy of Sciences signed the Agreement in 2022 and prepared its own Action Plan for 2024–2027 (*Czech Academy of Sciences, 2024*). This was a significant step because it publicly connected the Academy's internal evaluation procedures with a European reform movement. It also placed the Academy under a self-declared obligation to reflect on its own assessment practices. The Action Plan did not represent an external fashion adopted for symbolic reasons; it became a framework for refining a system of institute evaluation that had already existed for decades.

The four central principles associated with the Academy's reform are especially revealing. First, research assessment should recognise the diversity of contributions that research activity produces and through which it meets the needs of society. Second, assessment should be based on qualitative approaches in which informed peer review plays a central role. Third, inappropriate uses of publication metrics should be abandoned. 4th, international rankings should not be used to evaluate research organisations (*Czech Academy of Sciences, 2024*; *Coalition for Advancing Research Assessment, 2022*). These principles directly address the weaknesses of metric-driven evaluation. They also fit the Academy's disciplinary diversity. An institution containing physical sciences, life sciences, humanities, social sciences, technical fields, archives, libraries, observatories, and research infrastructures cannot be assessed through a single hierarchy of journal metrics or rankings. Reform therefore meant defending the intellectual plurality of the Academy against the administrative temptation of simplification.

The rejection of inappropriate metrics did not mean rejecting evidence. This distinction is crucial. The Academy's reform did not propose a return to informal academic reputation, personal authority, or closed disciplinary self-confirmation. Instead, it sought to strengthen expert judgement by using evidence responsibly. Selected outputs, institute reports, team profiles, bibliometric context, case studies, governance documents, strategy statements, and international comparisons can all inform evaluation. The point is that none of these should replace the careful reading and judgement of qualified experts. A publication should be assessed for what it contributes, not merely for the journal in which it appears. A research team should be assessed for its quality, originality, methodological rigour, future potential, and environment, not simply for the number of outputs it produces. The Academy's reform therefore moved from metric-centred visibility to evidence-informed understanding.

The evaluation of CAS institutes for the period 2020–2024 embodied this reorientation. It was designed as a large-scale qualitative informed peer-review exercise involving all research institutes and their research teams. International commissions were established for the institutes, and selected outputs were assessed by external experts. The procedure sought to evaluate not only the products of research but also their context, contribution, originality, significance, and methodological rigour (*Czech Academy of Sciences, 2026*). This was an important methodological shift because it separated the assessment of research contribution from the assessment of publication venue. In older metric cultures, the journal often became a proxy for the paper, and the quantity of papers became a proxy for team quality. In the reformed model, the work itself returned to the centre of attention. This was perhaps the most important intellectual meaning of the reform.

The use of one international panel for each institute in the 2020–2024 evaluation was institutionally significant. It recognised that each institute has a specific research profile, internal structure, disciplinary environment, and strategic context. A centralised panel covering an entire broad discipline might miss the particular character of an institute. By contrast, institute-specific international commissions could examine teams, outputs, infrastructure, management, interdisciplinary links, and developmental trajectories in a more coherent way. This approach also allowed reviewers to assess the institute as an organisation rather than only as an aggregation of outputs. The Academy's reform therefore strengthened the institutional dimension of evaluation. It asked not only whether individual results were good, but whether institutes were capable of sustaining high-quality research environments.

The distinction between evaluation of research teams and evaluation of institutes became more important in the 2020s. Research teams are the immediate sites of scientific production, methodological innovation, mentoring, and collaboration. Institutes are broader organisations with leadership, strategy, infrastructure, budgets, personnel policies, public responsibilities, and long-term missions. A team may be excellent inside an institute whose strategic governance is weak, while an institute may have a strong overall mission but uneven team quality. The reformed evaluation sought to capture this internal complexity. It separated the criteria and forms of feedback appropriate to teams from those appropriate to institutes. This distinction made evaluation more useful for management, because it provided information at the level where decisions about support, renewal, restructuring, and strategy are actually made.

A major innovation of the 2020s reform was the stronger formative character of evaluation. The purpose was not simply to rank institutes or generate a public league table. It was to provide qualified, actionable feedback identifying strengths, weaknesses, risks, and opportunities for future development (*Czech Academy of Sciences, 2026*). This shift is essential for understanding the reform. Ranking produces status, but it often provides little guidance for improvement. Formative evaluation, by contrast, treats assessment as part of institutional learning. It asks what an institute can do better, how it can strengthen research quality, where it faces strategic risks, and what kind of support or restructuring may be needed. For an Academy with long-term public responsibilities, this developmental function is more valuable than symbolic ranking.

The reform also strengthened the connection between evaluation and research integrity. Quality is not only a matter of originality or citation visibility; it also depends on ethical responsibility, methodological reliability, transparency, and sound research environments. The Academy's emphasis on evaluation as a tool for protecting investment in science and supporting the integrity of research reflects this wider understanding (*Czech Academy of Sciences, 2026*). In the 2020s, research integrity became increasingly connected with open science, data management, reproducibility, responsible authorship, and public trust. Evaluation therefore had to consider not only what was produced, but how it was produced. This broadened the meaning of scientific excellence. Excellence without integrity cannot serve either science or society.

The reform's attention to disciplinary context was particularly important for humanities and social sciences. These fields had long been vulnerable to evaluation models that privilege journal articles indexed in international databases, rapid output cycles, and citation patterns more typical of natural or biomedical sciences. A historian's monograph, a philosophical interpretation, a critical edition, a dictionary, an archaeological corpus, a sociological dataset, or a legal analysis may have long-term value that cannot be captured by journal quartiles. At the same time, the reform did not exempt these fields from international standards. It required expert panels capable of judging quality within disciplinary traditions and in relation to broader scholarly debates. The 2020s reform therefore offered humanities and social sciences a more appropriate but not less demanding evaluative framework. It defended their specificity while still insisting on intellectual seriousness.

In the natural, technical, and life sciences, the reform challenged the overuse of journal-based proxies without denying the importance of international publication. Researchers in these fields often work within global journal systems, and publication visibility remains an important

part of scientific communication. However, the Academy's reform emphasised that the quality of a paper cannot be inferred simply from the journal's Article Influence Score, impact factor, or quartile. Expert assessment must look at the actual contribution, originality, methodological rigour, and significance of the work (*Czech Academy of Sciences, 2026*; *DORA, 2013*). This position is especially important in fields where journal hierarchies can shape careers, funding, and internal prestige. The reform sought to reduce the dominance of proxy prestige and return attention to scientific substance.

The handling of applied research and societal relevance also changed. In the 2020–2024 evaluation, applied research results were assessed in context, including through case-based approaches in the later phase of evaluation (*Czech Academy of Sciences, 2026*). This was a significant improvement over systems that count patents, contracts, prototypes, or reports without examining their actual meaning. Applied research can contribute to technology, public policy, environmental management, health, heritage protection, education, and social resilience. But its value cannot be measured only by the existence of a formal output category. A case-study approach allows evaluators to ask what problem was addressed, who benefited, how knowledge was used, and whether the contribution was scientifically and socially meaningful. This approach aligned evaluation with the Academy's broader public mission.

The reform also had consequences for interdisciplinary research. Traditional evaluation systems often struggle with work that crosses disciplinary boundaries. Interdisciplinary outputs may not fit neatly into journal categories, panel structures, citation fields, or institutional departments. Yet many contemporary research problems, including climate change, digitalisation, health, cultural memory, energy, biodiversity, and social transformation, require interdisciplinary cooperation. The Academy's 2020s reform explicitly recognised the need to consider the diversity of institutes and teams, including interdisciplinary research (*Czech Academy of Sciences, 2024*). This was not only a methodological issue. It was a strategic matter for the Academy's future. An institution that wishes to address complex public problems must evaluate interdisciplinary work in ways that do not punish it for lacking a single disciplinary home.

The relationship between CAS evaluation and national Methodology 2025+ also deserves attention. Methodology 2025+ continued the modular architecture of Methodology 2017+ and strengthened the idea that evaluation should combine summative and formative functions. It maintained a common national framework while recognising the role of funding providers, including the Czech Academy of Sciences, in conducting provider-level evaluations adapted to their sectors (*Research on Research Institute, 2025*). This arrangement is important because it avoids both excessive fragmentation and excessive centralisation. The national level can provide comparability and accountability, while the Academy can apply institute-specific procedures suitable for its own mission. The 2020s reform therefore matured into a two-level system: national assessment for the broader R&D&I structure and Academy assessment for institutional learning and strategic development.

The grading of research organisations in national frameworks introduced another tension. Grades can be useful for funding allocation and strategic overview, but they can also compress complex institutional realities into a single symbol. The Academy's reform responded to this problem by emphasising rich feedback, expert reports, and developmental recommendations rather than only final categories. This distinction matters because a public research institute is not a school examination candidate. It is a complex organisation with heterogeneous teams,

infrastructures, public tasks, international relations, and long-term trajectories. A grade may help policymakers, but it cannot substitute for understanding. The reform of the 2020s therefore tried to preserve the informational depth of evaluation even when national systems required simplified outputs for funding or governance.

The costs of evaluation became an explicit concern. Large-scale international peer review requires time, money, administrative coordination, expert recruitment, conflict-of-interest management, documentation, translation, data preparation, and communication with institutes. It also demands substantial work from researchers, directors, administrators, and evaluation panels. The Academy's Action Plan acknowledged the need to find a balance between the benefits and costs of evaluation (*Czech Academy of Sciences, 2024*). This is a mature institutional insight. Evaluation should not consume so many resources that it weakens the research it is meant to improve. The reform therefore had to ask not only what should be assessed, but also how often, how deeply, and at what administrative cost. Responsible evaluation includes responsibility for the evaluative burden itself.

The role of international experts remained central but became more carefully structured. International peer review protects evaluation from localism and connects the Academy with global standards. However, the selection of experts, conflict-of-interest checks, and consistency across panels are crucial. The 2020–2024 evaluation involved international panels and remote external evaluators, with coordination mechanisms established to manage procedures and objections (*Czech Academy of Sciences, 2026*). This reflects the professionalisation of evaluation governance. Internationality alone does not guarantee fairness; it must be organised through transparent rules. The Academy's reform therefore combined external judgement with procedural safeguards. This combination was necessary if institutes were to trust the process even when conclusions were critical.

The reform also changed the meaning of transparency. Earlier evaluation systems often aimed at producing results for funding and governance. The 2020s reform increasingly treated transparency as part of research culture itself. Transparent criteria, clear documentation, published methodologies, action plans, and public communication help build trust in evaluation. They also allow researchers to understand how their work will be judged. However, transparency must be balanced with confidentiality where peer-review comments, sensitive institutional information, or personnel issues are involved. The Academy's challenge was to make evaluation publicly credible without turning it into public spectacle. The best form of transparency is not exposure for its own sake, but intelligibility of purpose, process, and use.

The reform of research evaluation in the 2020s also connected with career policy. If institutes are evaluated only through publication counts or journal prestige, then researchers, especially early-career researchers, are encouraged to shape their careers around those indicators. If evaluation recognises mentoring, team science, data practices, societal contribution, methodological innovation, interdisciplinarity, and responsible research culture, then career expectations can become broader and healthier. This is one reason why assessment reform is never merely institutional. It affects the professional imagination of researchers. The Academy's participation in CoARA and DORA principles therefore has consequences for recruitment, promotion, leadership development, and the evaluation of individual researchers, even when the formal exercise concerns institutes and teams. Institutional assessment and career culture are deeply connected.

The COVID-19 pandemic formed an important background to the 2020–2024 evaluation period. It disrupted research activity, mobility, fieldwork, laboratory access, conferences, archives, and international cooperation. It also highlighted the public importance of scientific expertise, from biomedical research and modelling to social analysis and communication. Evaluation of this period therefore could not be treated as a normal snapshot of stable conditions. It had to take account of institutional resilience, adaptability, and uneven pandemic effects across disciplines. Some fields could continue remotely; others were severely constrained by access to facilities, people, or sites. The reform's emphasis on context and expert judgement was especially valuable under such conditions. Mechanical indicators would have been particularly misleading in a period of systemic disruption.

The war in Ukraine and the wider crisis of European security also influenced the atmosphere of research evaluation in the 2020s. The Academy's international responsibility, support for researchers at risk, and cooperation with Ukrainian scholars became part of a broader understanding of science as a civic and European institution. Although evaluation is not primarily a foreign-policy instrument, it cannot be entirely separated from the values of openness, solidarity, integrity, and democratic responsibility. The 2020s reminded European research organisations that academic freedom and international cooperation are not guaranteed abstractions. They are institutional achievements that must be defended. The Academy's reform of evaluation therefore took place in a world where research quality, public trust, and democratic resilience were increasingly connected.

One of the most important conceptual shifts of the 2020s was the movement from evaluating outputs to evaluating contributions. An output is a publication, dataset, patent, report, edition, software tool, exhibition, or other identifiable product. A contribution asks a larger question: what did this work add to knowledge, method, society, infrastructure, policy, culture, or future research capacity? This shift is subtle but profound. It allows evaluators to recognise that the same type of output may have very different value in different contexts. It also prevents the category of output from becoming a fetish. The Academy's reform aimed to assess the substance, originality, significance, and context of research, not merely its formal container. In this respect, it belongs to a wider movement from bureaucratic accounting to evaluative judgement.

The reform also gave new significance to institutional strategy. In a complex research environment, institutes cannot simply accumulate projects and publications without a coherent sense of direction. Evaluation in the 2020s increasingly asked whether institutes had credible strategies, whether they could renew personnel, whether they were internationally positioned, whether they managed infrastructure responsibly, whether they cultivated early-career researchers, and whether they responded to previous recommendations. Strategy became part of quality because scientific excellence depends on organisational conditions. An institute may have excellent past achievements but weak future capacity if it lacks renewal, leadership, or strategic clarity. The Academy's reformed evaluation therefore helped connect past performance with future viability. This is one of the strongest reasons for treating evaluation as formative rather than merely summative.

At the same time, the reform did not eliminate all tensions. Peer review can be slow, expensive, and sometimes inconsistent. Qualitative judgement can produce disagreement. Institutes may perceive recommendations as insufficiently sensitive to local constraints. National funding systems may still require simplified grades or indicators. Researchers may still feel

pressure from metrics in grant competitions, journals, and career evaluations outside the Academy's direct control. CoARA and DORA principles can guide reform, but they do not automatically transform academic culture. The Academy therefore faces the difficult task of aligning its internal evaluation principles with the wider incentive structures of Czech and European science. Reform is not a single declaration; it is a continuing process of institutional learning.

The reform of the 2020s is also important because it shows the Academy's capacity for self-correction. A post-socialist institution could have defended its evaluation system as already mature and refused further change. Instead, the Academy acknowledged that evaluation must continue to evolve. This reflexive capacity is part of institutional modernisation. The Academy's evaluation system began in the early 1990s as a response to rupture, developed in the 2000s and 2010s as a mechanism of accountability and funding, and in the 2020s moved towards responsible, qualitative, and formative assessment. This trajectory reflects a broader institutional maturation. The Academy no longer had to prove merely that it could survive after socialism. It now had to prove that it could lead by example in the culture of research assessment.

The reform also reveals a deeper continuity in the Academy's modern history. Since 1993, the institution has repeatedly tried to balance autonomy and accountability. In the 1990s, this meant defending scientific freedom while accepting restructuring and public responsibility. In the 2000s, it meant adapting to competitive funding and formal evaluation. In the 2010s, it meant responding to national methodologies and performance-based governance. In the 2020s, it meant reforming evaluation itself so that accountability would not undermine the values of science. The form of the problem changed, but the underlying tension remained. The Academy's history can therefore be read as a continuous negotiation between independence, quality, state support, public trust, and international standards.

The consequences of the 2020s reform will become fully visible only over time. Evaluation reports can influence funding, leadership decisions, team restructuring, career policy, strategic priorities, interdisciplinary development, and cooperation with universities or public institutions. They can also shape how researchers understand what counts as good science. If the reform succeeds, it will encourage institutes to value quality over quantity, contribution over proxy prestige, and responsible research culture over superficial performance. If it fails, metrics may return through informal channels, administrative burden may grow, and peer review may become another ritual of compliance. The outcome will depend not only on methodology but on how Academy leadership, institute directors, panels, researchers, and policymakers use evaluation results. Reforming assessment is therefore also reforming institutional behaviour.

Thus, the reform of research evaluation in the 2020s marked a decisive stage in the modernisation of the Czech Academy of Sciences. It built on the Academy's long experience of internal evaluation since 1993, but redirected that experience towards qualitative, formative, internationally informed, and mission-sensitive assessment. Through Methodology 2017+, the emerging Methodology 2025+, CoARA commitments, DORA principles, and the 2020–2024 evaluation of CAS institutes, the Academy moved further away from the inappropriate use of publication metrics and proxy indicators. The reform sought to recognise the diversity of research contributions, the specificity of disciplines, the importance of societal relevance, and the need for actionable feedback rather than rankings. It did not abolish accountability; it made

accountability more intelligent. In doing so, it connected the Academy's post-socialist struggle for autonomy with the contemporary European movement for responsible research assessment and prepared the ground for future debates on open science, research integrity, career development, and public trust.

Internationalisation and European Integration

1. Participation in European Research Programmes

Participation in European research programmes became one of the principal instruments through which the Czech Academy of Sciences moved from post-socialist reintegration to full membership in the European research system. In the early 1990s, international cooperation still carried the emotional and political meaning of reopening after decades of restricted mobility and ideological supervision. By the late 1990s and especially after accession to the European Union, it increasingly became a structured mode of research governance. European programmes brought money, mobility, infrastructure, peer review, international consortia, reporting standards, and a new vocabulary of excellence, impact, work packages, coordination, and deliverables. For the Academy, this was not simply another source of funding. It was a profound institutional school in which institutes learned to operate according to European rules of scientific competition and cooperation. The Academy's participation in European programmes therefore connected several lines of its modernisation: internationalisation, funding reform, evaluation, career development, infrastructure building, and public accountability.

The beginning of this process should not be placed only in 2004, when the Czech Republic joined the European Union. Czech research teams entered European framework cooperation earlier, during the pre-accession period, when the country was still learning how to position itself within the emerging European research architecture. Reports from the Technology Centre of the Academy noted that Czech research and development teams participated in EC Framework Programmes and the Euratom programme from 1993, beginning with the Third Framework Programme (*Technology Centre AS CR, 2007*). Later, the Czech Republic's participation in the 5th Framework Programme from 1999 marked a more formal and politically visible stage of integration into European research policy (*European Commission, n.d.*). This chronology matters because it shows that Europeanisation began before full EU membership. The Academy and other Czech research organisations had to learn European project culture while still operating from the position of a transforming post-socialist state.

The pre-accession period had a formative character. Czech institutes were not yet fully embedded in European funding networks, and their administrative capacity was limited in comparison with long-established Western institutions. Researchers had to learn how to find calls, interpret programme priorities, build consortia, negotiate roles, prepare budgets, and satisfy reporting rules. These skills were not self-evident in a scientific culture that had only recently emerged from a planned and politically supervised system. The Academy's institutes possessed scientific expertise, but European programme participation required an additional

layer of organisational competence. Thus, the first phase of participation was not only about winning projects. It was about learning the grammar of European research cooperation. This learning process gradually changed the internal culture of institutes and the expectations placed upon their directors, researchers, and administrative staff.

The establishment of the Technology Centre of the Czech Academy of Sciences in 1994 was crucial in this development. The Centre became a national information and consultation body for EU Framework Programmes and later developed into a key organisation for research and innovation policy, European programme support, analysis, and advisory services (*Technology Centre Prague, n.d.*). Its existence showed that participation in European programmes could not be left to individual improvisation alone. Researchers needed specialised guidance, information channels, partner-search tools, training, and interpretation of programme rules. The Technology Centre helped create the infrastructure of European participation. It also became a bridge between research organisations, state administration, European institutions, and the evolving national research policy system. In this sense, it represented one of the most practical institutional responses to the challenge of Europeanisation.

For the Academy's institutes, the first European projects were often transformative even when they were modest in financial scale. They opened access to international partners, comparative data, specialised equipment, training opportunities, and collaborative publication. They also exposed Czech researchers to external standards of project design and assessment. A European project required more than a good idea. It required a consortium, defined objectives, division of labour, milestones, management structures, budgets, risk awareness, and communication plans. This did not always sit comfortably with academic habits formed in more autonomous or nationally focused research environments. Yet it taught institutes how to translate research potential into project architecture. Over time, this became a normal part of scientific practice.

The Framework Programmes also altered the relationship between national and European priorities. Academy institutes had to decide how their own research agendas could fit into European calls without losing intellectual autonomy. This required strategic translation. A laboratory working on materials, ecology, molecular biology, informatics, or energy could connect its research to European technological and societal challenges. A humanities or social-science institute could connect its work to questions of memory, migration, identity, governance, cultural heritage, social change, or European integration. The danger was that European programme priorities might encourage opportunistic adaptation to fashionable topics. The opportunity was that they allowed Czech researchers to situate nationally grounded expertise within wider European debates. The Academy's participation in European programmes therefore involved constant negotiation between local scholarly identity and transnational research agendas.

The European Union's Framework Programmes also brought a new competitive environment. Academy institutes were no longer competing only with Czech universities, national institutes, or domestic grant applicants. They were competing and cooperating with research organisations across Europe, many of which had stronger infrastructure, higher salaries, larger administrative offices, and longer experience in European consortia. This asymmetry was one of the structural challenges faced by post-socialist research systems. Czech teams could contribute real expertise, but they often had to overcome weaker visibility and limited project-management capacity. Participation in European programmes therefore both revealed and

helped reduce the gap between Czech science and older EU member states. The process was demanding because it required institutional upgrading under competitive conditions.

The accession of the Czech Republic to the European Union in 2004 changed the political and practical context of participation. European research programmes now became part of the country's normal membership obligations and opportunities rather than an external pre-accession instrument. For the Academy, this meant that European programme participation was no longer a sign of exceptional international openness. It became an expected dimension of institutional performance. Institutes were increasingly judged not only by domestic outputs and national grant success, but also by their ability to enter European networks. EU membership also strengthened access to European research infrastructures, mobility schemes, policy debates, and programme committees. The Academy's Europeanisation thus deepened from project participation into broader integration within the European Research Area.

The 6th Framework Programme and the 7th Framework Programme introduced Academy institutes more fully into the large-scale structures of European collaborative research. These programmes strengthened the role of multinational consortia and large projects, often combining universities, research organisations, enterprises, public bodies, and non-European partners. For Academy institutes, such projects could be scientifically productive and institutionally demanding. Participation required clear internal coordination, administrative support, financial management, intellectual property awareness, and communication with partners across different legal and organisational systems. It also required the ability to work in English as the practical language of project negotiation and reporting. The result was a gradual professionalisation of international research administration. European participation helped produce a new type of institutional competence inside the Academy.

The role of National Contact Points was especially important in this professionalisation. The Czech support system for European programmes provided information, consultations, monitoring, training, and methodological assistance to applicants and participants. This support helped reduce the disadvantage of institutions entering complex European funding mechanisms from a post-transformation starting point. For Academy institutes, such support could make the difference between isolated attempts and systematic participation. It also created feedback loops between researchers, support offices, national policy bodies, and European programme structures. Through this support system, European participation became less dependent on exceptional individual experience and more embedded in institutional routines. This was an important step towards the normalisation of European project culture.

Horizon 2020 marked another stage in the Academy's European participation. It combined excellent science, industrial leadership, and societal challenges, thereby linking frontier research with innovation and public-policy concerns (*European Commission, n.d.*). For the Academy, this structure was both an opportunity and a challenge. Institutes strong in fundamental research could pursue excellence-oriented instruments, while others could participate in challenge-driven consortia, research infrastructures, or applied collaborations. Horizon 2020 also increased the importance of impact narratives, open access requirements, data management, ethics, communication, and exploitation plans. These elements broadened the meaning of a research project beyond the production of scholarly results. Academy

institutes had to show how their research related to wider scientific, economic, societal, or policy environments.

The European Research Council became especially important for the Academy because it represented a model of excellence-driven, investigator-led European funding. ERC grants are designed to support frontier research proposed by individual principal investigators or small groups, selected through demanding peer review and international competition (*European Research Council, n.d.*). For the Academy, ERC success carried a symbolic importance beyond the size of a grant. It signalled that researchers based in Czech institutes could compete at the highest European level. It also helped attract talent, strengthen teams, and raise institutional visibility. ERC projects often changed the local research environment by bringing resources, international postdoctoral researchers, doctoral students, equipment, and intellectual prestige. In this sense, ERC participation became a marker of the Academy's transformation from a post-socialist successor institution into a European research actor.

The Academy's later creation of support structures for ERC applicants shows how European programmes influenced internal policy. CAS developed specialised support, including ERC-related advisory activities and the ERC Incubator, designed to help researchers across Academy institutes prepare high-quality proposals and improve their chances of success (*Czech Academy of Sciences, n.d.*; *Czech Academy of Sciences, 2026*). Such measures demonstrate that participation in European programmes had become a strategic priority rather than an individual adventure. The Academy recognised that success in ERC competitions requires time, mentoring, institutional backing, proposal development, mock interviews, and expert feedback. This support also reflects a broader shift in research management. Excellence is still judged internationally, but institutions can create conditions that make excellence more competitive. European programme participation therefore reshaped the Academy's internal instruments for supporting scientific ambition.

Marie Skłodowska-Curie Actions contributed differently, by focusing on mobility, training, career development, and international circulation of researchers. For the Academy, MSCA schemes helped attract foreign postdoctoral researchers, support outgoing and incoming mobility, strengthen doctoral and postdoctoral training, and connect institutes with international career paths. These actions were particularly important for early-career researchers, because they linked professional development with international experience. They also helped institutes become more cosmopolitan workplaces. A research institute that hosts MSCA fellows must provide supervision, training, integration, and administrative support. Thus, MSCA participation affected not only individual careers but also the social and organisational culture of institutes. It made international mobility part of everyday academic life.

European research infrastructures also became a major component of participation. Many contemporary scientific problems require facilities, data systems, instruments, repositories, observatories, and distributed platforms that exceed the capacity of a single institute or even a single country. Academy institutes in fields such as physics, biology, earth sciences, environmental research, digital humanities, and social data could benefit from European infrastructure networks. Participation in such infrastructures changed the scale of research. It also required long-term commitments, national co-financing, governance participation, technical standards, and data-sharing procedures. The Academy's role in European programmes therefore cannot be understood only through individual projects. It also involved

integration into material and digital systems that structure the production of modern knowledge.

The widening instruments of Horizon 2020 and Horizon Europe had particular relevance for the Czech Republic as part of the EU13 group of newer member states. These instruments aimed to reduce disparities in research and innovation performance within Europe by supporting teaming, twinning, ERA Chairs, excellence hubs, and other capacity-building measures. Academy institutes participated in this logic not as passive recipients of assistance, but as institutions seeking to strengthen excellence, attract talent, and build new research centres. The success of CAS institutes in ERA Chair calls, including projects in plant research and environmental and technology ethics, illustrates how widening instruments could support both natural sciences and humanities-oriented excellence (*Czech Academy of Sciences, 2024*; *Czech Academy of Sciences, 2024*). Such projects show that European programmes could help create new intellectual centres within the Academy. They also reveal how capacity-building instruments became part of the Academy's strategic renewal.

Horizon Europe, launched for 2021–2027, deepened these tendencies. It is the European Union's 9th framework programme for research and innovation and is structured around Excellent Science, Global Challenges and European Industrial Competitiveness, Innovative Europe, and Widening Participation and Strengthening the European Research Area (*European Commission, n.d.*). For the Academy, Horizon Europe provided a broad field of participation: ERC, MSCA, research infrastructures, clusters addressing global challenges, missions, partnerships, and widening instruments. Its structure fitted the Academy's diverse disciplinary profile. Institutes could participate in frontier research, climate and biodiversity work, health, digitalisation, social transformations, culture, security, energy, mobility, and other areas. Horizon Europe therefore reinforced the Academy's need to think strategically across disciplines rather than treating European projects as isolated opportunities.

The mission-oriented dimension of Horizon Europe deserves particular attention. Missions were designed to address major societal challenges, such as climate adaptation, cancer, oceans and waters, climate-neutral cities, and soil health. The involvement of a scientist from the Global Change Research Institute of the Academy in a Horizon Europe Mission Board on soil health and food symbolised a new level of participation in European research policy, not only European research projects (*Czech Academy of Sciences, 2019*). This is important because the Academy's European role cannot be reduced to receiving grants. It also includes contributing expertise to the shaping of European agendas. When Academy researchers participate in boards, panels, advisory structures, or programme committees, they help define the problems that European research seeks to solve. This represents a more mature form of integration into the European Research Area.

Participation in European programmes also affected the Academy's internal understanding of impact. In national academic traditions, the value of research was often discussed in terms of scholarly contribution, cultural significance, or service to national knowledge. European programmes introduced a more explicit requirement to explain potential impact on society, economy, policy, environment, technology, and public life. This requirement could sometimes feel artificial or managerial, especially for fundamental research. Yet it also encouraged researchers to think more clearly about pathways from knowledge to use. For the Academy, whose mission includes both international-level research and attention to the needs of Czech society and national culture, the European impact agenda was not foreign in principle (*Czech*

Academy of Sciences, n.d.). The challenge was to translate impact without reducing science to short-term utility. Participation in European programmes helped develop this more nuanced language of public relevance.

The European programmes also strengthened the relationship between research and open science. Horizon 2020 and Horizon Europe gradually expanded expectations concerning open access, data management, FAIR principles, repositories, and responsible dissemination. These requirements influenced Academy institutes by making publication and data practices part of project compliance and research culture. Open science was not simply an ideological slogan; it became embedded in grant agreements, reporting rules, and evaluation expectations. For institutes with strong publication cultures, this required new administrative and library support. For fields working with sensitive data, archives, cultural heritage, or personal information, it required careful ethical and legal management. European programme participation therefore helped prepare the Academy for the broader open science agenda discussed later in this chapter.

European programme participation also strengthened cooperation between the Academy and Czech universities. Many EU projects require consortia with complementary expertise, infrastructure, training capacity, and societal partners. Academy institutes and universities therefore often entered projects together, sometimes alongside hospitals, enterprises, ministries, regional authorities, or foreign partners. Such cooperation helped soften the older separation between Academy research and university teaching. It also supported joint doctoral training, shared laboratories, interdisciplinary centres, and common international strategies. European projects could therefore function as bridges within the Czech research system. They created practical incentives for collaboration where institutional histories had sometimes encouraged separation or competition.

The role of enterprises and applied partners increased through European research and innovation programmes. The Academy's primary mission remained research across natural, technical, social sciences, and humanities, but many institutes possessed knowledge relevant to technology, medicine, environment, materials, energy, digital tools, and public policy. European projects often required cooperation with industry, SMEs, public authorities, or civil-society organisations. This pushed institutes to develop capacities in knowledge transfer, intellectual property, contracts, exploitation planning, and stakeholder communication. The Academy had to preserve its fundamental research identity while learning how to collaborate in innovation-oriented settings. European programmes thus contributed to the broader transformation from an isolated research system towards an interconnected knowledge ecosystem.

European participation also created administrative pressures. The preparation and management of EU projects required professional grant offices, legal support, financial control, audit readiness, procurement knowledge, reporting systems, and communication capacity. Researchers could not manage these tasks alone without compromising their scientific work. Institutes therefore had to invest in specialised administrative staff. This changed the internal sociology of the Academy. Project managers, international officers, financial administrators, lawyers, communication specialists, and data stewards became increasingly important to research success. European participation therefore professionalised not only researchers but also the institutional environment around research. This was one of the less visible but decisive effects of European integration.

The Academy's participation in European programmes also had a generational effect. Younger researchers increasingly encountered European calls, mobility schemes, ERC ambitions, MSCA fellowships, and international consortia early in their careers. This changed professional expectations. A successful research career in the Academy could no longer be imagined only within national publication and institutional promotion. It increasingly required international mobility, English-language communication, project experience, external funding, and participation in transnational networks. This created new opportunities but also new pressures. Early-career researchers could build independent profiles through European schemes, but they also faced competition, temporary contracts, and the need to demonstrate mobility and international visibility. European programmes therefore became part of the human dimension of modernisation.

The Academy's European participation also intersected with the problem of brain circulation. European mobility could produce brain drain if talented researchers left Czech institutes permanently for better-funded systems. Yet European programmes also created mechanisms for return, reintegration, and attraction of foreign talent. MSCA, ERC, ERA Chairs, and institutional support programmes could help build teams in Czech institutes and make them attractive to researchers from abroad. The key issue was whether mobility would become a one-way loss or a circulation of people, methods, networks, and ideas. The Academy's later initiatives to support excellence, careers, and ERC applications show that it recognised this strategic challenge (*Czech Academy of Sciences, 2026*). Participation in European programmes therefore forced the Academy to connect internationalisation with personnel policy.

The unequal participation of newer EU member states in European research programmes remained a structural challenge. Studies of EU13 participation have repeatedly noted lower success rates, weaker coordination roles, and persistent asymmetries between older and newer member states (*European Commission, 2024*; *Lepori, Reale, & Slipersæter, 2015*). The Czech Academy operated within this broader context. Its institutes could achieve excellent results, but the national system as a whole faced challenges of salary competitiveness, infrastructure gaps, limited administrative capacity, and weaker historical embeddedness in European networks. This meant that every European success had both scientific and symbolic meaning. It demonstrated that a Czech public research institute could overcome structural disadvantages and participate in European science at a high level. At the same time, the asymmetry reminded policymakers that excellence requires long-term investment.

European programmes also made coordination roles more important. Participation as a partner is valuable, but coordination demonstrates a higher level of trust, capacity, and leadership. Coordinating a European project requires intellectual leadership, administrative competence, financial responsibility, and the ability to manage diverse partners. For Academy institutes, moving from participation to coordination represented a more advanced form of European integration. It showed that Czech teams could help shape research agendas rather than only contribute to agendas designed elsewhere. This shift was gradual and uneven, but strategically important. The Academy's long-term European position depends not only on the number of projects in which its institutes participate, but also on their ability to lead consortia, host ERC principal investigators, manage infrastructures, and influence programme priorities.

Participation in multilateral European schemes beyond the main Framework Programme also mattered. The Academy's Head Office directly administers involvement in ERA-NET Cofund

activities such as NORFACE and HERA, as well as other multilateral platforms connecting European and non-European partners (*Czech Academy of Sciences, n.d.*). These schemes are important because they support fields and collaborations that may not fit easily into the largest framework calls. NORFACE and HERA, for example, have been especially relevant for social sciences and humanities, where European cooperation often concerns comparative societies, cultural heritage, memory, identity, and social transformation. Multilateral schemes therefore helped ensure that European participation was not limited to laboratory sciences and technological innovation. They widened the Academy's European integration across its disciplinary spectrum.

The humanities and social sciences benefited from European programmes in distinctive ways. Their participation often involved comparative research, archival cooperation, conceptual exchange, cultural heritage, migration, memory studies, democracy, social cohesion, populism, or European identities. Such projects helped Czech scholarship move beyond national isolation while preserving its own sources and questions. European funding could support collaboration with partners who brought different historical experiences and theoretical traditions. It could also help overcome the old post-socialist stereotype that Central European humanities were mainly national or descriptive. Through European projects, CAS institutes in these fields could contribute to general debates about Europe, society, culture, and politics. This was an important intellectual expansion of their public role.

In the natural and technical sciences, European programmes often offered access to larger experimental networks, technology platforms, data systems, and interdisciplinary consortia. CAS institutes working in physics, chemistry, biology, ecology, informatics, materials science, and biomedicine could use European projects to connect local expertise with global research problems. Participation in such projects could strengthen equipment, attract researchers, and raise publication visibility. It could also expose teams to highly demanding standards of project delivery and international collaboration. The Academy's success in these areas helped demonstrate that its institute-based model remained compatible with modern European science. European programmes therefore reinforced the Academy's argument that specialised public research institutes have a continuing role alongside universities.

The Academy's involvement in European science advice also illustrates the broadening of programme participation. SAPEA, Science Advice for Policy by European Academies, is part of the European Commission's Scientific Advice Mechanism and has been funded through Horizon 2020 (*Czech Academy of Sciences, 2019*). Participation in such structures links the Academy not only to research projects but also to the European policy-advice ecosystem. It shows that academies are valued as sources of multidisciplinary expertise, including engineering, humanities, medicine, natural sciences, and social sciences. For the Czech Academy, this kind of involvement is consistent with its self-understanding as a body serving both scholarship and society. It also demonstrates how European programmes can support the civic role of academies, not only their laboratory research.

European programmes also changed the Academy's communication culture. Projects increasingly required websites, public summaries, dissemination plans, stakeholder engagement, policy briefs, open days, exhibitions, and media communication. Researchers had to explain their work to audiences beyond their immediate disciplines. This did not always come naturally to fields shaped by specialised scholarly communication. Yet it helped the Academy develop a more outward-facing research culture. European project communication

contributed to the later emphasis on transparency, open science, and public accountability. In this sense, participation in European programmes influenced the Academy's relationship with society as well as with foreign partners.

Financially, European programmes diversified the resource base of Academy institutes. EU grants could provide substantial funding for personnel, mobility, equipment, networking, training, and coordination. However, they also required co-financing, cash-flow management, audit compliance, and careful budgeting. They could strengthen institutes, but they could not replace stable institutional funding. A research organisation dependent only on projects risks fragmentation and short-termism. The Academy therefore had to integrate European grants into a broader funding portfolio that included institutional support, national grants, internal Academy instruments, and applied or contractual funding. European participation was strongest when it reinforced long-term institutional strategy rather than becoming a patchwork of disconnected projects.

The evaluation effects of European participation were significant. Success in European programmes became a sign of international competitiveness and was often considered in institutional assessment. ERC grants, MSCA fellowships, Horizon consortia, ERA Chairs, infrastructure participation, and coordination roles provided evidence that institutes could meet external standards. Yet these indicators had to be interpreted carefully. Some fields have more opportunities in European programmes than others; some excellent research may not fit current European calls; and grant success depends partly on administrative capacity and programme priorities. Still, European participation became one of the important signals of research vitality. It linked internationalisation, funding, and evaluation in a concrete way.

By the 2020s, the Academy's participation in European programmes had become sufficiently mature to require dedicated strategic support. CAS maintained ERA-oriented information structures, ERC support, multilateral cooperation mechanisms, and links with the Technology Centre Prague. These structures reveal a shift from reactive participation to proactive positioning. The Academy no longer merely responded to calls as they appeared. It increasingly sought to prepare researchers, develop institutional capacity, identify strategic opportunities, and align European participation with long-term scientific priorities. This is a major difference from the 1990s, when European programme culture was still new and often unfamiliar. By the 2020s, European participation had become one of the ordinary languages of Academy governance.

This maturity does not mean that all problems disappeared. Administrative burden, low success rates, competition with better-resourced institutions, salary gaps, uneven participation among institutes, and the challenge of coordinating large projects remained serious issues. European programmes can sometimes push researchers towards fashionable themes, excessive reporting, or impact narratives that do not fit fundamental inquiry. They can also deepen inequalities between strong and weaker institutes if support is not carefully distributed. The Academy's task has been to use European programmes as instruments of quality and integration without allowing them to dominate scientific priorities mechanically. This balance remains one of the central questions of modernisation.

Participation in European research programmes ultimately changed the Academy's place in Czech society. It demonstrated that Czech public research could contribute to European agendas and compete internationally. It brought foreign researchers, ideas, standards, and networks into Czech institutes. It strengthened the Academy's argument for stable public

investment by showing that institutional support could leverage European resources and international recognition. It also linked Czech scientific expertise with European responses to climate change, health, digitalisation, cultural heritage, social transformation, energy, and democratic resilience. The Academy's European participation therefore was not merely an external dimension of its work. It became one of the mechanisms through which the Academy redefined its national public mission in European terms.

Thus, participation in European research programmes was a decisive component of the Czech Academy of Sciences' modernisation after 1993. It began before EU accession, developed through the Framework Programmes, deepened after 2004, and matured through Horizon 2020 and Horizon Europe. European programmes transformed the Academy's funding environment, international partnerships, administrative capacities, evaluation culture, career structures, infrastructure participation, and public communication. They created opportunities for excellence through ERC grants, mobility through MSCA, capacity building through widening instruments, and societal engagement through mission-oriented and challenge-driven projects. At the same time, they exposed the Academy to structural asymmetries, administrative burdens, and the danger of project-driven fragmentation. The Academy's achievement lay in gradually transforming European programme participation from an external opportunity into an internal element of institutional strategy. In doing so, it became not only a Czech research organisation with international contacts, but a European research actor embedded in the evolving architecture of the European Research Area.

2. International Mobility, Cooperation, and Project Networks

International mobility, cooperation, and project networks became one of the most visible signs that the Czech Academy of Sciences had moved beyond the first phase of post-socialist recovery. In the early 1990s, international mobility was still experienced as liberation from the restrictions of the previous regime. By the 2000s and 2010s, it had become a normal condition of scientific work, career development, project participation, and institutional evaluation. The Academy's internationalisation was therefore not only a matter of signing agreements or joining European programmes. It changed the social and professional texture of research life. Researchers travelled more frequently, foreign colleagues entered Czech laboratories and archives, doctoral students and postdoctoral fellows acquired international experience, and institutes learned to operate through networks rather than isolated national structures. Mobility became a mechanism through which ideas, methods, standards, instruments, and academic habits circulated. This movement did not eliminate national responsibilities or institutional identities, but it placed them within a wider field of cooperation. The modern Academy gradually became a node in a dense international system of visits, grants, workshops, consortia, advisory bodies, infrastructures, and long-term partnerships.

The post-1989 reopening of mobility had a special psychological and symbolic importance. Under state socialism, foreign travel was never merely a professional matter. It was filtered through political trust, institutional control, foreign-policy orientation, and sometimes security suspicion. After the Velvet Revolution, the ability to leave, return, invite, collaborate, and publish abroad became part of the recovery of academic freedom. For many researchers, international mobility meant the restoration of a normal scholarly biography. Conferences, archive visits, laboratory placements, research stays, and informal meetings again became ordinary components of intellectual life. Yet the freedom to move also revealed the damage

produced by decades of constrained exchange. Some disciplines had lost direct contact with contemporary debates; others had maintained scientific standards but lacked infrastructure, language confidence, or access to modern methods. Mobility therefore served both as a symbol of freedom and as a practical instrument of catching up. It connected moral transformation with the everyday rebuilding of professional competence.

The legal and institutional framework of the new Academy allowed this process to develop. The Act establishing the Czech Academy of Sciences recognised that the Academy and its institutes could conclude agreements on international cooperation in scientific activity and technological development (*Czech National Council, 1992*). This provision was important because it normalised international cooperation as part of the Academy's public mission. Institutes did not have to wait for political permission in the old sense; they could build partnerships related to their scientific profiles. This decentralised capacity was crucial, since genuine cooperation usually begins in concrete research environments rather than in ceremonial declarations. A physicist seeks access to an instrument, a historian needs an archive, a biologist needs a method, a linguist needs a corpus, and a sociologist needs comparative data. The Academy's internationalisation therefore developed through both central agreements and institute-level initiative. This combination became one of the characteristic features of the post-1993 period.

Bilateral cooperation formed the backbone of the Academy's mobility system. Agreements with partner organisations abroad created regular channels through which research teams could organise visits, joint work, workshops, and the preparation of larger projects. The CAS system of Mobility Projects and Mobility Plus Projects was designed precisely to establish or intensify scientific cooperation, support joint outputs, enable access to unique infrastructure and complementary methods, and prepare larger international projects (*Czech Academy of Sciences, n.d.*; *Czech Academy of Sciences, n.d.*). This model is significant because it treats mobility not as tourism or academic courtesy, but as a strategic investment in research capacity. A visit is valuable when it produces new methods, shared publications, better project proposals, access to equipment, or long-term cooperation. Mobility therefore became a bridge between personal contact and institutional development. It helped transform isolated international relations into durable research networks.

The distinction between ordinary mobility and project-oriented mobility is important. In the first years after 1989, short visits and invitations were often enough to restore communication. Later, mobility increasingly had to be embedded in research design. A visit abroad had to contribute to a defined project, a team relationship, a grant proposal, a shared dataset, or the development of a research infrastructure. This did not diminish the human meaning of mobility; rather, it gave it institutional weight. International travel became part of the production of knowledge, not merely a reward for established scholars. Young researchers learned techniques in foreign laboratories, archival scholars consulted collections abroad, and teams used mobility to coordinate multinational projects. The Academy's mobility schemes therefore helped professionalise international cooperation. They also linked mobility with evaluation, since sustained and productive international cooperation became one of the signs of institute vitality.

Mobility also changed the internal hierarchy of skills in Academy institutes. Scientific excellence was no longer separable from the ability to communicate internationally, write in English or other major scholarly languages, understand foreign funding systems, build

consortia, and work across institutional cultures. This did not mean that Czech-language scholarship lost its value. In many humanities and social-science fields, Czech remained essential for national scholarly responsibility, cultural interpretation, legal expertise, and public communication. Nevertheless, researchers increasingly had to operate bilingually or multilingually. International project networks required a practical command of English, familiarity with European administrative vocabulary, and the ability to translate local research questions into internationally intelligible forms. Mobility therefore reshaped the professional habitus of researchers. It produced a more outward-facing academic culture, though not without pressure and inequality.

The Academy's cooperation with neighbouring countries retained particular importance. Relations with Slovakia remained unusually close because Czech and Slovak science had shared an institutional history within Czechoslovakia. After 1993, cooperation with Slovak partners became international in legal terms but continued to be marked by linguistic proximity, disciplinary continuity, personal networks, and common archives. This was especially important in fields such as history, linguistics, archaeology, social sciences, environmental research, and regional studies. Czech-Slovak mobility did not have the exotic or symbolic character of reopening to the West, but it helped preserve a shared Central European scholarly space. It also showed that internationalisation does not always mean distance. Sometimes it means maintaining and renewing a formerly internal relationship under new state conditions. The Academy's cooperation with Slovakia thus represented continuity within institutional rupture.

Cooperation with Germany, Austria, Poland, Hungary, France, the United Kingdom, and other European partners gradually produced a more complex map of mobility. Germany was important because of its scientific strength, geographical proximity, and research organisations such as the Max Planck Society, the Leibniz Association, Helmholtz centres, and universities. Austria mattered as a neighbouring country with strong historical and regional connections to Czech scholarship. Poland and Hungary belonged to the broader Central European space of post-socialist transformation and shared research challenges. France provided important links in the humanities, social sciences, and natural sciences, including institutional platforms such as CEFRES. The United Kingdom and the United States offered access to globally influential academic environments, especially for postdoctoral training and publication culture. The Academy's mobility networks therefore developed as a layered geography of cooperation: neighbouring, regional, European, transatlantic, and global.

The role of CEFRES illustrates how mobility could create institutional spaces rather than only individual exchanges. The French Research Centre in Humanities and Social Sciences in Prague became a venue for cooperation among French, Czech, and Central European researchers. The later CEFRES Platform, involving CEFRES, Charles University, the Czech Academy of Sciences, and CNRS, showed how international cooperation could be embedded in a durable research environment (*Czech Academy of Sciences, n.d.*; *CEFRES, n.d.*). Such platforms matter because they combine mobility, doctoral training, seminars, joint projects, and intellectual exchange. They allow researchers to pass through an institution repeatedly, not merely visit once. For humanities and social sciences, where discussion, archives, language, and conceptual translation are central, these platforms can have a transformative effect. They help build international communities around topics rather than only around funding calls.

The Academy's fellowships also played a strategic role in incoming mobility. The J. E. Purkyně Fellowship was designed to attract outstanding creative scientists from abroad, including Czech scientists who had worked abroad for long periods and top foreign scientists, to CAS institutes for up to five years (*Czech Academy of Sciences, n.d.*). This type of fellowship addressed a major problem of post-socialist science: how to reverse or compensate for brain drain and how to bring internationally experienced researchers into Czech institutes. It also helped create local centres of excellence by giving institutes the means to recruit strong personalities. Such incoming mobility could change a laboratory or research group more deeply than a short visit. It brought new standards of mentoring, project leadership, publication practice, and international networking. The fellowship therefore linked mobility with institutional renewal.

The Josef Dobrovský Fellowship had a different but equally significant profile. It supported short-term study stays of foreign researchers at CAS institutes for work requiring knowledge of Czech historical, cultural, linguistic, geographical, or natural characteristics (*Czech Academy of Sciences, n.d.*). This programme is especially important for understanding the Academy's dual mission. On the one hand, it opened Czech institutes to foreign scholars. On the other hand, it strengthened Czech studies and research grounded in national or territorial specificity. It therefore showed that internationalisation does not have to erase national scholarly identity. Foreign researchers came to Czech archives, libraries, collections, landscapes, linguistic materials, and cultural resources because these local materials had international intellectual value. The fellowship thus turned Czech specificity into a basis for international cooperation.

Mobility in the Academy increasingly included doctoral and early-career researchers. This was one of the most important generational changes after 1989. Under the previous regime, younger researchers often depended on senior patronage and institutional permission to travel. In the modern period, doctoral students and postdoctoral fellows became expected participants in international mobility. They attended summer schools, spent time in foreign laboratories, joined European projects, co-authored publications with international teams, and learned research cultures abroad. This changed the meaning of academic apprenticeship. A young scientist was no longer trained only within a national institute or university department. Training increasingly involved movement across borders, exposure to different supervisory styles, and participation in international networks. The Academy's future therefore became connected with the capacity to make such mobility productive rather than accidental.

Marie Skłodowska-Curie Actions and other European mobility schemes deepened this generational shift. They supported doctoral networks, postdoctoral fellowships, staff exchanges, and international training environments. For CAS institutes, these schemes offered opportunities to host foreign researchers, send Czech researchers abroad, and participate in structured training networks. They also introduced expectations concerning supervision, career development, transferable skills, open science, ethics, and international recruitment. Mobility was no longer a simple individual stay; it became part of a programme of career formation. This was especially important for early-career researchers seeking to build independent profiles. European mobility schemes therefore connected internationalisation with the human dimension of modernisation. They helped transform the Academy from a set of national institutes into a set of training environments embedded in European research careers.

Project networks became increasingly important because modern research often requires cooperation among many institutions. A European consortium in climate research, materials science, digital humanities, social transformation, public health, or biodiversity is not merely a collection of partners. It is an organisational form through which scientific questions are divided, coordinated, funded, and communicated. Academy institutes had to learn to enter such networks as credible partners and, increasingly, as coordinators or leaders. Project networks demanded administrative competence, legal awareness, data management, intellectual property rules, and communication strategies. They also required researchers to work with different institutional cultures, from universities and academies to enterprises, hospitals, museums, NGOs, and public authorities. The Academy's participation in project networks therefore expanded its social and organisational world.

The movement from bilateral cooperation to multilateral networks was one of the defining features of the 2000s and 2010s. Bilateral mobility remains useful for establishing trust and developing focused cooperation, but many European research problems require larger networks. CAS multilateral cooperation schemes were designed to strengthen European cooperation with selected third countries and to facilitate the creation of new consortia capable of applying for funding under EU Framework Programmes (*Czech Academy of Sciences, n.d.*). This reveals the strategic role of smaller cooperative instruments. A mobility project or multilateral seed project may not be large in itself, but it can prepare the ground for a Horizon consortium, a joint infrastructure, or a long-term comparative research agenda. The Academy's network-building therefore developed through stages: contact, mobility, joint output, consortium, larger project, and sometimes permanent institutional partnership.

Research infrastructures gave cooperation networks a material foundation. Many fields now depend on instruments, databases, observatories, repositories, collections, laboratories, and digital platforms that no single institution can maintain alone. CAS institutes participate in research infrastructures both as users and as providers of specialised facilities. International mobility around infrastructures is often highly practical. Researchers travel to use an instrument, learn a protocol, access a dataset, calibrate equipment, or develop a method. Such cooperation is different from conference travel because it is embedded in the material conditions of research. It also creates long-term dependencies and obligations. Infrastructure networks therefore make international cooperation more durable, but also more complex and administratively demanding.

The humanities and social sciences have their own forms of infrastructure and networked cooperation. Archives, libraries, corpora, oral-history collections, archaeological databases, museum collections, digital editions, legal sources, and cultural heritage repositories can all become nodes of international research. Foreign scholars come to Czech institutes not only for discussion but also for access to materials that cannot be reproduced elsewhere. Czech researchers travel to foreign archives and collections for similar reasons. Digitalisation has expanded these possibilities, but it has not removed the importance of physical mobility. Working with manuscripts, artefacts, landscapes, oral-history witnesses, or local collections often still requires presence. The Academy's cooperation networks in the humanities therefore combine old and new forms of scholarly movement: archival travel, seminars, digital platforms, joint editions, comparative projects, and research schools.

International mobility also contributed to the reform of evaluation culture. Institutes that regularly hosted foreign researchers, sent staff abroad, participated in joint projects, and

published with international partners could demonstrate openness and vitality. Evaluation panels increasingly considered international cooperation as one element of research quality and institutional strategy. This did not mean that every foreign contact was automatically valuable. Ceremonial agreements, superficial co-authorships, or unfocused visits could not substitute for strong research. Nevertheless, productive mobility became evidence that an institute was connected to active scientific communities beyond the national system. It also helped reviewers judge whether institutes were aware of international standards in their fields. Mobility and evaluation therefore became mutually reinforcing elements of modernisation.

At the same time, international mobility introduced new inequalities. Not all researchers could travel equally. Family responsibilities, language barriers, health, age, teaching obligations, project commitments, visa issues, and financial constraints shaped access to mobility. Younger researchers might be expected to move frequently, but precarious contracts could make mobility risky. Women researchers could face particular difficulties when mobility expectations collided with unequal care responsibilities. Researchers in well-funded laboratory fields might have more travel resources than colleagues in underfunded humanities areas. Internationalisation therefore did not automatically produce fairness. The Academy's human-resource policies had to recognise that mobility is both an opportunity and a selective pressure. A modern institution cannot simply praise mobility; it must make mobility accessible and meaningful.

Brain drain remained a persistent risk throughout the post-1993 period. The opening of borders allowed talented Czech researchers to build careers in stronger research systems with higher salaries, better equipment, and more predictable career paths. Some departures were permanent, and they represented a real loss to Czech science. Yet mobility also created diaspora networks, return migration, joint supervision, co-authorship, and transnational careers. The J. E. Purkyně Fellowship and similar instruments were partly designed to turn outward mobility into circulation rather than loss (*Czech Academy of Sciences, n.d.*). The challenge was to create conditions under which researchers trained abroad would want to return or remain connected to Czech institutes. This required not only patriotic appeal, but competitive research environments, institutional support, project opportunities, and career prospects. Mobility therefore forced the Academy to confront the material conditions of scientific work.

International cooperation also became a form of science diplomacy. Academies have long served as institutions that connect states and societies through scholarly exchange, even when political relations are strained. The Czech Academy's membership in European academy networks such as ALLEA and EASAC placed it within a system of international scientific representation and policy advice (*ALLEA, n.d.*; *EASAC, n.d.*). These networks are not ordinary research consortia. They bring together academies as institutions that represent broad scientific communities and provide expertise on issues such as climate, energy, health, biodiversity, digital transformation, and research integrity. Through such networks, the Academy participates in the European public sphere of knowledge. It is not only a recipient of European projects, but also a contributor to European scientific advice.

SAPEA strengthened this advisory dimension. Science Advice for Policy by European Academies connects academy networks and provides evidence reviews for the European Commission's Scientific Advice Mechanism (*ALLEA, n.d.*; *SAPEA, n.d.*). For the Czech Academy, participation in this ecosystem is important because it links research excellence

with public responsibility at the European level. It also reflects a broader transformation in the role of academies. They are no longer only learned societies or collections of institutes; they are institutions expected to mediate between science, policy, and society. Cooperation networks therefore include not only laboratories and projects, but also expert panels, evidence-review groups, advisory boards, and policy dialogues. Internationalisation becomes part of public accountability.

The Academy's international cooperation also acquired an ethical dimension in the 2020s. The Russian full-scale invasion of Ukraine in 2022 forced European research institutions to respond to a direct attack on academic life, infrastructure, mobility, and personal safety. CAS introduced the Researchers at Risk Fellowship to support researchers and PhD students whose scientific work was threatened by war, persecution, or other dangers, initially focusing on Ukraine and later extending the idea to researchers from other countries where freedom of research is threatened (*Czech Academy of Sciences, 2022*; *Czech Academy of Sciences, 2024*; *Czech Academy of Sciences, n.d.*). This programme shows that mobility is not always voluntary career enhancement. Sometimes it is emergency protection. The Academy's support for at-risk researchers connected international cooperation with academic freedom, humanitarian responsibility, and democratic values. It also placed CAS within the wider European response to threats against science.

This ethical turn did not replace scientific criteria, but it widened the meaning of internationalisation. A threatened researcher hosted by a CAS institute must be able to continue scientific work in a safe environment, join a team, access infrastructure, and maintain professional identity. Such support is both humanitarian and scholarly. It prevents the destruction of scientific careers and preserves intellectual capacity that may later contribute to reconstruction in the researcher's home country. The programme also affects host institutes, which must integrate displaced researchers into ongoing work. International mobility therefore becomes a test of institutional solidarity. It shows whether a research organisation understands academic freedom not only as a national privilege but as a transnational responsibility.

International cooperation with non-European partners also expanded during the modern period. The Academy's bilateral partner organisations include academies and research institutions beyond the European Union, and Mobility Plus Projects have been used to support cooperation with partners in various regions (*Czech Academy of Sciences, n.d.*). Such cooperation reflects the globalisation of science beyond the framework of European integration. Czech researchers work with partners in Asia, the Americas, and other regions in fields ranging from natural sciences and engineering to archaeology, linguistics, area studies, and environmental research. These links are important because they prevent Europeanisation from becoming a closed continental horizon. The Academy's international networks have to be European in institutional architecture but global in scientific imagination. This balance is especially important in disciplines dealing with climate, biodiversity, health, migration, technology, and cultural exchange.

Cooperation networks also changed the everyday management of institutes. Directors and research leaders had to think in terms of international portfolios: bilateral agreements, EU projects, visiting scholars, doctoral mobility, ERC ambitions, MSCA fellows, infrastructure partnerships, and strategic alliances. Administrative staff had to support travel, visas, contracts, financial reporting, insurance, intellectual property, and data protection. Libraries

and IT departments had to support access to digital resources and remote cooperation. Communication offices had to publicise international achievements. Internationalisation therefore became distributed across the entire institution. It was no longer the responsibility of one foreign-relations office. It became a condition of normal institute functioning.

Digital communication transformed cooperation networks, especially after the COVID-19 pandemic. Online seminars, hybrid conferences, shared repositories, remote collaboration tools, and digital project management reduced some barriers to international cooperation. They also revealed that mobility is not only physical. Researchers can collaborate without travelling, supervise students across borders, share data, and participate in meetings remotely. Yet the pandemic also showed the limits of digital substitution. Laboratory work, fieldwork, archival research, trust-building, mentoring, and informal intellectual exchange often still require physical presence. The modern Academy therefore entered a hybrid regime of cooperation. Mobility became more selective but also more strategically combined with digital communication. This hybridisation is one of the new standards of research culture in the 2020s.

International project networks contributed to interdisciplinarity. Many contemporary European and global challenges cannot be addressed by one discipline alone. Climate change, public health, ageing, digitalisation, energy transition, cultural heritage protection, migration, and democratic resilience require cooperation across natural sciences, technical fields, social sciences, and humanities. CAS institutes, organised across three broad scientific areas, possess the disciplinary diversity needed for such cooperation. International projects often push institutes to connect fields that might otherwise remain institutionally separate. This can be difficult because interdisciplinary cooperation requires translation between methods, publication cultures, and evaluative expectations. Yet it is one of the major ways in which the Academy's internal structure becomes connected to external problems. Project networks therefore serve as bridges between disciplines as well as between countries.

The development of cooperation networks also influenced the Academy's public image. A research institution that hosts foreign scholars, participates in European advisory bodies, coordinates international projects, and supports researchers at risk appears not as an inherited national bureaucracy but as an active participant in global knowledge production. This matters for public legitimacy. The Academy has had to justify its role in Czech society, especially as a publicly funded non-university research system. International cooperation provides one form of evidence that its institutes are competitive, useful, and respected. However, this public image must be grounded in real research rather than ceremonial internationalism. The strongest legitimacy comes from cooperation that produces serious knowledge, trains researchers, solves problems, and contributes to society.

International mobility also affected the relationship between the Academy and Czech universities. Many mobility and project schemes involve doctoral students, university partners, joint supervision, shared laboratories, and consortia combining CAS institutes with university faculties. This helped overcome older institutional separations between research institutes and teaching universities. The Academy's institutes became attractive places for doctoral and postdoctoral training, while universities provided degree structures and teaching environments. International projects often required both types of institution, and mobility schemes created practical incentives for cooperation. Thus, internationalisation indirectly

supported the integration of the Czech research system. It showed that Academy-university relations could be strengthened through shared external networks.

The Academy's cooperation networks also required attention to research integrity and responsible partnership. International projects involve questions of authorship, data ownership, ethical approval, export controls, dual-use technologies, intellectual property, and unequal power relations between partners. As cooperation expanded beyond traditional academic exchange, the need for clear standards increased. European programmes, academy networks, and institutional policies all contributed to a more formal culture of responsible collaboration. This was especially important in sensitive areas such as health data, environmental monitoring, artificial intelligence, security, and cooperation with partners in authoritarian or unstable contexts. Internationalisation therefore increased not only opportunities but also ethical complexity. A modern Academy had to become capable of managing that complexity.

By the mid-2020s, international mobility and cooperation had become deeply embedded in the Academy's institutional life. CAS maintained bilateral and multilateral schemes, fellowships for incoming researchers, support for Czech studies, programmes for researchers at risk, participation in European academy networks, and project-based cooperation through Horizon Europe and related instruments. The result was a dense ecosystem rather than a single policy. Some instruments served short visits; others supported long-term recruitment. Some aimed at young researchers; others at established scholars. Some focused on Czech studies; others on frontier science, infrastructure, policy advice, or emergency protection. This variety is important because no single form of mobility can serve all purposes. The Academy's internationalisation matured by recognising the plurality of cooperation itself.

The meaning of project networks also changed over time. In the 1990s, international cooperation often helped Czech science reconnect with standards and partners from which it had been partly isolated. In the 2000s, it helped the Academy enter European programme structures. In the 2010s, it supported excellence, infrastructures, and strategic consortia. In the 2020s, it increasingly connected science with societal challenges, open science, research integrity, and academic freedom. This chronology shows that internationalisation is not a static condition. It changes as science, politics, technology, and society change. The Academy's task has been to adapt without losing its core mission: to conduct high-quality research across a broad spectrum of sciences and humanities while considering the needs of Czech society and national culture (*Czech Academy of Sciences, n.d.*).

Thus, international mobility, cooperation, and project networks transformed the Czech Academy of Sciences from a national institution recovering from political isolation into a research organisation embedded in European and global scientific circulation. Mobility restored academic freedom after 1989, but over time it became a strategic mechanism for building quality, training researchers, accessing infrastructure, creating consortia, attracting talent, and supporting scientists at risk. Bilateral agreements, Mobility Projects, Mobility Plus Projects, fellowships, European schemes, academy networks, and multilateral project structures all contributed to this transformation. The process brought opportunities, but also inequalities, administrative burdens, brain-drain risks, ethical dilemmas, and new demands on institute governance. Its deeper significance lies in the fact that internationalisation changed the Academy's internal culture. Research became more mobile, networked, comparative, multilingual, evaluative, and publicly accountable. In this sense, international

mobility was not an external supplement to the Academy's modernisation; it was one of the mechanisms through which modernisation became lived practice inside the institutes themselves.

3. AV ČR in the European Research Area

The position of the Czech Academy of Sciences in the European Research Area represents one of the most important outcomes of its post-1993 modernisation. The Academy did not enter the European Research Area as a newly created institution without memory, nor as a simple remnant of the socialist academy model. It entered as a restructured public research organisation carrying several historical layers: the legacy of Czech learned societies, the institutional inheritance of ČSAV, the democratic reconstitution of 1993, and the reform experience of the 1990s and 2000s. The European Research Area gave these layers a new framework. It required the Academy to think not only as a national institution of science, but also as a participant in a European system of knowledge production, mobility, infrastructures, careers, evaluation, open science, and research policy. This did not mean that the Academy abandoned its Czech public mission. Rather, it had to reinterpret that mission within a wider European space. AV ČR thus became one of the institutions through which Czech science entered the practical, political, and intellectual architecture of European research governance.

The European Research Area was conceived as more than a funding environment. It was meant to create a more coherent research space in Europe by reducing fragmentation, supporting mobility, strengthening excellence, improving coordination, and connecting national systems with European priorities (*European Commission, 2025*). For the Czech Academy, this vision had a special resonance. During the socialist period, Czech science had been embedded in a politically controlled international order, with privileged links to the Soviet bloc and limited access to many Western networks. After 1989, the first task was reopening. After 2004, the task became integration. By the 2020s, the task was no longer merely to participate in European programmes, but to influence, use, and critically assess the European Research Area as a framework for institutional development. This shift from participation to agency is central to understanding the Academy's modern role.

AV ČR's formal mission already corresponds closely to the logic of the European Research Area. The Statutes of the Czech Academy of Sciences state that the Academy conducts research through its institutes across natural, technical, social, and human sciences, pursues the advancement of knowledge at the international level, educates researchers, and applies its results for education, culture, competitiveness, and the solution of current societal problems (*Czech Academy of Sciences, n.d.*). This formulation combines three elements that are also central to the ERA: international excellence, human capital, and societal relevance. It also preserves the national dimension of the Academy's mission, especially in relation to Czech society and culture. The Academy is therefore not a purely Europeanised research platform detached from its country. It is a Czech institution whose capacity to serve national society depends increasingly on its ability to operate within European research structures.

The Academy's integration into the ERA developed through several overlapping channels. The first was participation in EU Framework Programmes, from pre-accession involvement in earlier programmes to full participation in Horizon 2020 and Horizon Europe. The second was mobility, including bilateral schemes, fellowships, European networks, and international

career instruments. The third was institutional representation in European policy and academy networks. The 4th was alignment with ERA standards in evaluation, open science, research integrity, infrastructures, gender equality, and career policy. These channels cannot be separated neatly. A Horizon Europe project may involve mobility, data policy, open access, infrastructure access, and career development at the same time. The ERA therefore entered the Academy not as one policy field, but as a dense set of expectations shaping research practice.

The creation and work of the European Research Area section at the CAS Head Office, OMS-ERA, shows how deeply European integration became institutionalised. OMS-ERA monitors European science policy and foreign funding opportunities, prepares information for CAS institutes, comments on legislative documents discussed at EU level, prepares CAS position papers, supports project managers at CAS institutes, assists ERC applicants, and administers multilateral cooperation activities such as ERA-NET Cofund schemes (*Czech Academy of Sciences, n.d.*). This is not merely an administrative service. It is an institutional mechanism for translating European policy into Academy practice and Academy interests into European debates. Without such structures, ERA participation would remain dependent on individual researchers or institute-level improvisation. OMS-ERA shows that the Academy understood the ERA as a policy space requiring professional attention, not simply as a catalogue of grant calls.

The Academy's position papers on the future of the European Research Area demonstrate that AV ČR did not approach European integration passively. It welcomed the ambition to create a coherent research area, but also criticised discrepancies between the declared purpose of the ERA and the complexity of the EU funding landscape (*Czech Academy of Sciences, 2021*). The Academy argued that fragmented European funding schemes can lead to overlapping efforts and confusion for applicants. This criticism is important because it shows the Academy speaking not only as a recipient of European policy but as an experienced research organisation capable of identifying structural problems in that policy. Such a stance reflects institutional maturity. A post-socialist institution seeking integration might have been tempted to treat European frameworks as unquestionable. AV ČR's position was more sophisticated: it supported Europeanisation, but also defended simplification, coherence, and usability.

This critical participation is one of the clearest signs that the Academy had become an actor within the ERA. To be in the European Research Area does not mean merely to accept European rules. It means to contribute to the shaping of those rules through evidence, experience, and institutional voice. CAS representatives participate in European science-policy discussions, advisory bodies, academy networks, and programme-related consultations. Such participation helps ensure that the perspective of a Central European public research organisation is not absent from debates often dominated by larger Western European systems. It also helps the Academy understand policy changes early and prepare its institutes for them. The ERA is therefore both an environment and a forum. AV ČR's role in it is both adaptive and representational.

The relationship between AV ČR and Horizon Europe illustrates this dual role. Horizon Europe is the EU's key research and innovation funding programme for 2021–2027 and supports collaboration, the dissemination of excellent knowledge and technologies, policy implementation, competitiveness, and the strengthening of the European Research Area (*European Commission, 2021*). For the Academy, Horizon Europe is not only a financial source.

It is one of the practical engines through which ERA principles enter institute life. It promotes international consortia, research infrastructures, missions, partnerships, open science, responsible research, and widening participation. CAS institutes participate in this system as research performers, project partners, coordinators, hosts of researchers, infrastructure actors, and sometimes contributors to advisory structures. Horizon Europe thus operationalises the ERA for the Academy.

However, participation in Horizon Europe also reveals the structural inequalities within the European Research Area. The ERA is formally conceived as a common research space, but European research systems differ greatly in historical resources, salary levels, administrative support, infrastructure, publication visibility, and capacity to coordinate large projects. Institutions from newer member states often face difficulties in competing with older, better-funded systems. The Academy has strong research teams and internationally respected institutes, but it operates within a national funding environment that cannot always match the resources available to leading Western European organisations. This creates a permanent tension. The Academy must compete in a European arena that is open in principle but unequal in practice. Its ERA strategy therefore necessarily combines ambition with a demand for more balanced access to excellence.

The EU's widening participation instruments are especially relevant in this context. They are designed to reduce disparities in research and innovation performance across Europe and to help institutions from less research-intensive countries build excellence and networks. For AV ČR, these instruments can support recruitment, institutional upgrading, international partnerships, and the development of new centres of expertise. Yet widening cannot be understood as charity. The Academy's strongest institutes do not need symbolic inclusion; they need fair opportunities, stable national co-investment, and access to high-level partnerships. Widening instruments are most effective when they strengthen already existing scientific potential and help it become structurally sustainable. In this sense, the Academy's role in the ERA is not that of a peripheral beneficiary, but of an institution seeking to transform uneven European integration into genuine scientific capacity.

The Academy's institute-based structure gives it a distinctive position in the European Research Area. Many European research systems are dominated by universities, while AV ČR consists of specialised public research institutes covering a broad disciplinary spectrum. This structure has advantages in the ERA. Institutes can concentrate expertise, maintain long-term programmes, manage specialised infrastructure, and respond flexibly to international project opportunities. At the same time, institute-based research must constantly negotiate its relationship with universities, doctoral training, and national higher education systems. The ERA encourages mobility and cooperation across institutional boundaries, which can strengthen collaboration between CAS institutes and Czech universities. Thus, AV ČR's presence in the ERA also reshapes domestic research relations. European integration pushes the Czech system towards more networked forms of cooperation.

Research infrastructures are one of the most important areas where the Academy's institute model aligns with ERA priorities. The ERA Policy Agenda 2025–2027 identifies research infrastructures as a long-term structural policy area, alongside open science, careers, assessment reform, gender equality, knowledge valorisation, and other priorities (*European Commission, 2025*). Many CAS institutes maintain or use facilities, collections, instruments, databases, observatories, and specialised platforms that are meaningful beyond the borders

of one institution. European infrastructure participation allows Czech researchers to access facilities abroad and foreign researchers to use Czech capacities. It also raises questions of sustainability, governance, data standards, and long-term investment. In this field, the Academy can contribute not only scientific expertise but also institutional continuity. Infrastructures require patience, planning, and trust, qualities that a stable public research organisation can provide.

Open science became another key area linking AV ČR to the ERA. The European Research Area increasingly treats open access, FAIR data, repositories, transparency, and responsible dissemination as elements of modern research culture. For the Academy, open science is not only an external requirement attached to European projects. It affects libraries, publishing practices, data management, evaluation, research integrity, and scholarly communication. CAS institutes work across fields with very different data cultures: experimental data, environmental observations, archival materials, linguistic corpora, social data, historical sources, and sensitive biomedical information. The ERA's open science agenda therefore requires institutional interpretation. The Academy has to support openness while respecting ethical, legal, disciplinary, and cultural constraints. This is precisely the kind of complexity that modern ERA participation entails.

Research careers form another major point of connection between AV ČR and the ERA. The ERA Policy Agenda 2025–2027 includes research careers among its structural policies and links them with talent attraction, mobility, and career development (*European Commission, 2025*). For the Academy, this issue is especially important because its future depends on generational renewal, postdoctoral opportunities, international recruitment, return mobility, and the retention of excellent researchers. European instruments such as Marie Skłodowska-Curie Actions, ERC grants, ERA Chairs, and mobility schemes can support these aims. Yet European career expectations also create pressure. Researchers are increasingly expected to be mobile, internationally visible, grant-successful, and productive across multiple dimensions. AV ČR must therefore translate the ERA career agenda into policies that support excellence without producing excessive precarity.

The Academy's involvement in ERC support shows how ERA participation becomes internal career policy. ERC grants are one of the strongest symbols of European research excellence, and CAS has developed support mechanisms for ERC applicants through its Head Office and related expert structures (*Czech Academy of Sciences, n.d.*). This support reflects a realistic understanding of European competition. Excellence alone may not be enough if researchers lack mentoring, proposal experience, institutional backing, and preparation for interviews. By building ERC support, the Academy turns a European funding instrument into an internal mechanism of talent development. The aim is not simply to obtain grants. It is to cultivate researchers capable of formulating ambitious projects at the European frontier. ERC participation therefore links the ERA with the Academy's internal culture of excellence.

Research assessment reform connects the Academy to another major ERA agenda. The movement towards responsible assessment, reflected in CoARA and in the Academy's own Action Plan, aligns CAS evaluation practices with European debates on qualitative peer review, the responsible use of indicators, and recognition of diverse research contributions (*Coalition for Advancing Research Assessment, 2022*; *Czech Academy of Sciences, 2024*). This is not a peripheral matter. Evaluation shapes careers, funding, institute strategy, and scholarly behaviour. By participating in European assessment reform, AV ČR contributes to the

redefinition of excellence in a way that is particularly important for a diverse academy containing both laboratory sciences and humanities. The ERA thus becomes a space where the Academy can defend a broad understanding of research quality. It can argue that world-class science cannot be reduced to journal metrics or rankings.

Gender equality and institutional culture also belong to the ERA framework. European research policy increasingly expects research organisations to address gender balance, leadership diversity, working conditions, and inclusive career environments. For AV ČR, these expectations intersect with its own post-socialist institutional history and the generational transformation of research careers. The Academy's modernisation cannot be measured only by grants and publications. It also depends on who can become a researcher, who can lead teams, whose careers are interrupted, and how institutes manage work-life balance, mobility expectations, and leadership pipelines. The ERA places these questions within a European framework and gives them policy visibility. This does not solve them automatically, but it makes them harder to ignore.

Knowledge valorisation is another ERA priority with particular relevance for AV ČR. The Academy has traditionally been associated with basic research, but many of its institutes produce knowledge relevant to industry, public administration, health, environment, cultural heritage, security, and education. European policy increasingly asks how research results are transferred, used, communicated, and embedded in society. The Academy's Strategy AV21, with its emphasis on "top research in the public interest", can be read as a Czech institutional answer to this European question (*Czech Academy of Sciences, n.d.*; *Czech Academy of Sciences, 2026*). It connects institutes, universities, industrial partners, state bodies, and the public sector around socially important topics. In this way, AV ČR translates the ERA's concern with impact and societal relevance into a national programme rooted in its own structure.

Strategy AV21 is especially important because it prevents Europeanisation from becoming purely external. The Academy does not simply import European priorities; it formulates its own interdisciplinary programmes that connect high-quality research with public needs. These programmes create consortia across CAS institutes and with partners outside the Academy. They address issues such as health, energy, society, environment, technologies, cultural heritage, and public policy. This is close to the mission-oriented logic of Horizon Europe, but it is shaped by Czech institutional conditions. Strategy AV21 therefore shows the Academy's ability to domesticate ERA principles. It transforms European ideas of public value, interdisciplinarity, and problem-oriented research into an Academy-specific mechanism of coordination.

The Academy's participation in European academy networks also strengthens its role in the ERA. Through organisations such as ALLEA, EASAC, and SAPEA, academies contribute to European science advice, research integrity, policy statements, and evidence synthesis (*ALLEA, n.d.*; *EASAC, n.d.*; *SAPEA, n.d.*). AV ČR's involvement in these networks places it within a community of institutions that speak not only for individual projects but for science as a public good. This is an older role of academies, but in the ERA it acquires new policy significance. European research governance needs not only funders and universities, but also bodies capable of offering broad, multidisciplinary, and relatively independent scientific advice. AV ČR's participation in such networks therefore extends its role from research performance to research representation.

Science for policy has become increasingly important in the European Research Area. The ERA Policy Agenda 2025–2027 explicitly includes science for policy among the areas of action and structural development (*European Commission, 2025*). This priority corresponds to one of the Academy's long-term strengths: the capacity to provide expert knowledge across many fields. CAS institutes can contribute to public policy through environmental analysis, health research, social science, legal expertise, cultural heritage, energy studies, technology assessment, and risk analysis. European science-for-policy frameworks broaden the audience for such expertise. They also create standards for evidence review, transparency, and communication with policymakers. The Academy's role in the ERA thus includes the translation of specialised knowledge into public decision-making.

The Russian invasion of Ukraine in 2022 gave the Academy's European role a sharper ethical and political meaning. AV ČR condemned the aggression, expressed support for Ukrainian colleagues, and prepared fellowship support for students, postdoctoral researchers, and scientists from Ukraine (*Czech Academy of Sciences, 2022*). This action was not merely bilateral assistance. It reflected the values underlying the European Research Area: academic freedom, international solidarity, openness, and the defence of research communities under threat. The war also showed that the ERA is not only a technocratic policy space. It is embedded in the political conditions of democracy, security, and freedom. AV ČR's support for researchers at risk therefore belongs to its European identity as much as to its humanitarian responsibility.

The European Research Area also raises questions of research security. In the 2020s, European science policy became more attentive to risks associated with geopolitical dependence, dual-use technologies, foreign interference, data security, and cooperation with authoritarian contexts. For AV ČR, these questions are delicate because science depends on openness and international collaboration, but openness must be combined with responsibility. The Academy's broad disciplinary structure means that research security cannot be reduced to one field. It may concern advanced technologies, biomedical data, artificial intelligence, environmental information, strategic materials, or politically sensitive social research. The ERA provides a forum in which these issues can be discussed collectively. AV ČR's task is to incorporate security awareness without undermining the openness that makes science possible.

The Academy's public research institute model gives it a particular responsibility within Czech participation in the ERA. Universities educate large numbers of students and play a central role in doctoral training. Businesses contribute to innovation and applied development. Ministries shape policy and funding. AV ČR contributes concentrated research capacity, long-term expertise, scientific infrastructure, and interdisciplinary programmes. Its place in the ERA must therefore be understood through complementarity rather than competition. The Academy is not a university substitute, nor merely a grant contractor. It is a national research institution whose European value lies in the combination of depth, continuity, disciplinary breadth, and public mission. This distinctive profile allows it to contribute to ERA goals in ways that differ from other Czech actors.

The Academy's ERA integration also affects its relationship with Czech society. European participation can sometimes appear distant from national public concerns, especially when programmes use abstract policy language or complex administrative categories. AV ČR has to show that participation in the ERA strengthens its ability to serve Czech society rather than

diverting attention away from it. This is where the Academy's dual mission becomes crucial. International excellence and national relevance are not opposites. European networks can improve Czech environmental policy, health research, technological capability, cultural heritage protection, education, and democratic resilience. The Academy's challenge is to make these connections visible. ERA participation must be translated into public value.

At the same time, the Academy must avoid reducing its European role to immediate utility. The ERA supports excellent knowledge, research infrastructures, careers, open science, and long-term innovation capacity, not only short-term solutions. AV ČR's strongest contribution may often lie in basic research whose social value appears only later. Mathematics, theoretical physics, molecular biology, archaeology, linguistics, philosophy, or long-term ecological monitoring cannot always be justified by immediate application. Yet the European Research Area depends precisely on such depth. The Academy therefore has to defend the place of fundamental inquiry within European policy frameworks increasingly oriented towards competitiveness and societal challenges. Its role is to remind the ERA that useful science often begins as free, curiosity-driven research.

The relationship between European competitiveness and scientific autonomy is one of the central tensions of the 2020s. Horizon Europe and the ERA increasingly emphasise competitiveness, technology, strategic autonomy, industrial transformation, and response to global challenges (*European Commission, 2021*). These aims are legitimate, especially in a world of technological rivalry and ecological crisis. Yet the Academy must ensure that competitiveness does not become the only language of value. Its mission includes education, culture, knowledge, and the solution of societal problems, not merely economic growth. AV ČR's participation in the ERA should therefore be understood as a negotiation between European policy priorities and the broader intellectual mission of science. The Academy strengthens Europe not only by producing innovation, but by preserving independent research capacity.

The Academy's experience also illustrates that the European Research Area is not a finished reality. It remains a project marked by fragmentation, inequality, administrative complexity, and uneven implementation. AV ČR's critique of fragmented European funding reflects this unfinished character (*Czech Academy of Sciences, 2021*). The existence of ERA agendas, forums, and policy actions does not by itself create a seamless European research space. Researchers still face different national salaries, pension systems, career structures, evaluation cultures, legal rules, and administrative burdens. Institutes from different countries have unequal access to networks and resources. The Academy's practical experience therefore provides an important corrective to overly optimistic descriptions of the ERA. Integration is real, but incomplete.

By the mid-2020s, however, AV ČR had become deeply embedded in ERA structures. Its institutes participated in European projects, infrastructures, missions, partnerships, mobility schemes, and advisory networks. Its Head Office monitored European policy, supported ERC applicants, trained project managers, and prepared position papers. Its evaluation reforms aligned with European research-assessment debates. Its Strategy AV21 translated public-interest research into an Academy-wide coordination mechanism. Its support for Ukrainian researchers and researchers at risk linked international cooperation with academic freedom. These developments show that the Academy's Europeanisation was not limited to one

administrative domain. It entered the Academy's funding, governance, values, communication, careers, and public mission.

The place of AV ČR in the European Research Area therefore represents a mature stage of the institutional history traced throughout this project. Earlier chapters emphasised the Academy's emergence from learned societies, its socialist formation as ČSAV, its ideological deformation, its normalisation, its democratic rupture in 1989, and its post-1993 stabilisation. In the ERA, all these earlier layers acquire a new meaning. The Academy's struggle for autonomy becomes part of a European debate on academic freedom and responsible assessment. Its disciplinary breadth becomes relevant to interdisciplinary European challenges. Its national cultural mission becomes compatible with European cultural and scientific cooperation. Its public accountability becomes linked to open science, research integrity, and societal relevance. The ERA therefore does not replace the Academy's history; it reframes it.

Thus, AV ČR's position in the European Research Area should be understood as the outcome of a long transformation from post-socialist recovery to European agency. The Academy entered the ERA through programmes, mobility, partnerships, and evaluation reforms, but gradually became more than a participant in external schemes. It developed structures for monitoring and influencing European policy, supported ERC and Horizon participation, joined European academy networks, aligned assessment and open-science practices with wider reforms, and translated European priorities into its own Strategy AV21. At the same time, it preserved a distinct national mission rooted in Czech society, culture, and long-term scholarly responsibility. The Academy's role in the ERA therefore lies in a productive tension: it is simultaneously Czech and European, autonomous and accountable, basic-research oriented and publicly engaged, historically grounded and future-facing. This tension is not a weakness. It is precisely the form through which a modern academy of sciences can contribute to Europe's knowledge system while remaining responsible to its own society.

Open Science, Digitalisation, and New Standards of Research Culture

1. Open Access and Research Data Policies

Open access and research data policies became one of the clearest signs that the modernisation of the Czech Academy of Sciences had entered a new phase. In the 1990s, the Academy had to rebuild autonomy, stabilise institutes, defend public funding, and reconnect with international research. In the 2000s and 2010s, it had to adapt to competitive grants, evaluation mechanisms, European programmes, and project networks. By the 2020s, however, the question was no longer only who produced research, how it was funded, or how it was evaluated. It was also how research results circulated, who could access them, under what conditions they could be reused, and what responsibilities publicly funded science had towards society. Open science therefore did not appear as an isolated technical reform of libraries or repositories. It emerged as a new norm of research culture, linking transparency,

reproducibility, public accountability, digital infrastructure, intellectual property, data governance, and the European Research Area.

The Czech Academy's open science agenda should be understood as a continuation of its post-1989 transformation rather than as a sudden fashion imported from Brussels. The Academy's democratic legitimacy after 1993 depended on the claim that publicly funded research served society while preserving scientific autonomy. Open access gave this claim a new practical form. If research is supported by public money, its results should, wherever possible, be accessible to other researchers, institutions, teachers, students, policymakers, enterprises, journalists, and citizens. This principle does not mean that every document, dataset, or method can be made public without restriction. It means that closure must be justified rather than assumed. In this sense, open science transformed the moral economy of public research. Knowledge produced within public institutions was increasingly treated not as an internal possession of institutes or journals, but as a shared intellectual resource.

The Academy had already moved in this direction before the full vocabulary of open science became dominant. Its earlier Open Access Policy, approved in 2010, belonged to a period when the main concern was access to publications. That policy reflected the growing dissatisfaction across Europe with subscription barriers, expensive journal packages, and the paradox that publicly funded research often became inaccessible to the public because it was locked behind commercial paywalls. For Academy institutes, open access was initially connected above all with scholarly communication and institutional repositories. It concerned articles, books, reports, and publication metadata. Yet even this early phase was significant. It required researchers to think about rights, versions, repositories, publisher contracts, and the public visibility of their work. It also placed the Library of the Czech Academy of Sciences in a more strategic role as a coordinator of research information.

The later Open Science Principles of the Czech Academy of Sciences, approved in 2024, represented a broader and more mature stage of this development. They replaced the earlier Open Access Policy and expanded the focus from publications to the openness of the research cycle as a whole (*Czech Academy of Sciences, 2024*). The document linked open access, research data, software, metadata, repositories, licensing, FAIR principles, and institutional support. This change reflected the wider transformation of European research culture. Open science no longer meant only that a published article should be readable without payment. It also meant that data should be managed responsibly, that code and tools should be shared where possible, that outputs should be reusable, and that research practices should become more transparent. The Academy's move from open access to open science therefore marked an important conceptual enlargement.

The principle "as open as possible, as closed as necessary" became central to this policy culture. It is a deliberately balanced formula. It rejects both secrecy by default and naive total openness. In scientific practice, some materials cannot be fully opened because of personal data protection, intellectual property, security concerns, ethical obligations, contractual restrictions, cultural sensitivity, endangered species locations, archaeological site protection, or the rights of research participants. At the same time, such restrictions should not be used as a convenient excuse for withholding data that could reasonably be shared. The formula therefore requires judgement. It asks researchers and institutes to identify what can be opened, what must remain closed, and what can be shared under controlled or delayed

conditions. This is especially important for an Academy whose institutes work across very different fields and data cultures.

The FAIR principles became another foundation of the Academy's research data policy. FAIR means that data should be findable, accessible, interoperable, and reusable (*Wilkinson et al., 2016*). These principles are often misunderstood as identical with open data, but they are not the same thing. Data can be FAIR even when access is restricted, provided that metadata, conditions, identifiers, formats, and reuse rules are clear. This distinction is essential for fields dealing with sensitive biomedical data, personal information, protected cultural heritage, or legally restricted materials. For the Academy, FAIR therefore offered a practical language for improving data governance without ignoring legitimate constraints. It moved the discussion beyond the simple opposition between open and closed. The central question became whether research data are managed in a way that makes them discoverable, understandable, preserved, and reusable under appropriate conditions.

Data management plans became one of the principal instruments through which this culture entered research practice. A data management plan asks researchers to think at the beginning of a project about what data will be collected, how they will be described, where they will be stored, who will have access, what formats will be used, what ethical or legal restrictions apply, and how long-term preservation will be ensured. This is a major shift from older habits in which data management often occurred informally, locally, and sometimes only at the end of a project. The Academy's open science policy encouraged institutes to manage data according to FAIR principles and to use trusted repositories within the timeframes specified in the data management plan (*Czech Academy of Sciences, 2024*). In practical terms, this meant that data stewardship became part of scientific professionalism. A well-designed project now had to include not only research questions and methods, but also a plan for the responsible life of the data it produced.

The Library of the Czech Academy of Sciences acquired a central role in this transformation. Libraries in modern research organisations are no longer merely places where books and journals are stored. They are infrastructures for access, metadata, repositories, licensing, digital preservation, bibliometrics, research information, and open science support. The creation of a specialised Open Science Department at the Library strengthened this role and gave institutes a point of contact for advice on open access, research data management, data management plans, and compliance with funders' requirements (*Czech Academy of Sciences, 2025*). This institutional support was necessary because open science cannot be implemented only through declarations. Researchers need practical tools, templates, consultations, training, and legal guidance. Without such support, open science risks becoming an additional administrative burden rather than a meaningful improvement in research culture.

The ASEP institutional repository became a key component of the Academy's open access infrastructure. Deposit of publications in ASEP helped ensure that outputs of CAS institutes were recorded, discoverable, and, where permitted, accessible. The Open Science Principles recommended that CAS employees deposit the version of record or the author accepted manuscript at the time of publication at the latest (*Czech Academy of Sciences, 2024*). This recommendation matters because repository deposit preserves institutional memory and reduces dependence on commercial platforms. It also supports evaluation, visibility, and public access. For an Academy composed of many specialised institutes, a common

repository helps create a shared record of research activity. It connects institute-level work with the Academy's public responsibility as a whole.

Open access also changed the relationship between authors and publishers. Under traditional publishing models, researchers often transferred rights to publishers and then found themselves unable to share their own work freely. Open access policies therefore required attention to copyright, licences, embargoes, author accepted manuscripts, and rights retention. The Academy's emphasis on Creative Commons licences, especially CC BY or equivalent licences where appropriate, reflected the need to make reuse conditions transparent (*Czech Academy of Sciences, 2024*). This was not merely a legal technicality. It defined what readers, researchers, teachers, and digital systems could do with published material. Open access is strongest when it allows not only reading but also lawful reuse, quotation, teaching, text and data mining, translation, and integration into new research. The licence therefore became part of scholarly communication.

European policy strongly reinforced these institutional changes. Horizon Europe treats open science as a central mode of research practice and requires open access to publications as well as open access to research data under the principle "as open as possible, as closed as necessary" (*European Commission, 2021*). For Academy researchers participating in European projects, open science was not optional rhetoric. It was part of grant compliance, proposal evaluation, reporting, and project management. This changed behaviour inside institutes. Researchers had to understand open access routes, data management plans, repository choices, FAIR data, metadata, ethics, and reuse conditions. European funding therefore helped translate open science from a general value into daily administrative and methodological practice. It also connected the Academy's internal policies with the European Research Area.

The European Open Science Cloud gave the data dimension of this agenda an infrastructural horizon. EOSC was designed to support access to research data, services, tools, and infrastructure across Europe, creating conditions for data-intensive and cross-disciplinary science. For the Czech research system, EOSC also encouraged the development of national data infrastructure and coordination. CESNET, an association of universities and the Czech Academy of Sciences, plays a key role in the Czech e-infrastructure environment and has been identified as the national mandated organisation in EOSC-related structures (*EOSC Association, 2025*). This matters for the Academy because open data cannot exist without secure storage, identifiers, metadata standards, interoperability, computing capacity, and long-term preservation. Open science is therefore as much about infrastructure as it is about ideals. It requires a material and digital system capable of keeping knowledge usable.

The Czech national policy environment also shaped the Academy's open science development. The National Strategy for Open Access to Scientific Information of the Czech Republic for 2017–2020 and its action plan helped place open access and data issues within national research policy (*Government of the Czech Republic, 2017*; *Government of the Czech Republic, 2019*). Later, Act No. 241/2022 Coll. amended the public R&D support framework and introduced obligations concerning research data produced in publicly funded projects announced after August 2022 (*Parliament of the Czech Republic, 2022*). These changes show that open science was no longer only an institutional preference of the Academy or a condition of European projects. It became part of the legal and policy architecture of Czech research.

The Academy's own principles therefore emerged in dialogue with national law, European policy, and international recommendations.

UNESCO's Recommendation on Open Science gave this agenda a global normative framework. It defined open science as an inclusive construct combining open scientific knowledge, open science infrastructures, science communication, open engagement of societal actors, and dialogue with other knowledge systems (*UNESCO, 2021*). This broader understanding is important because it prevents open science from being reduced to repository deposit or publication fees. It links openness with equity, participation, collaboration, and trust. For the Czech Academy, the UNESCO framework reinforced the idea that open science is part of scientific responsibility. An academy of sciences is not only a producer of expert knowledge. It is also a public institution that helps shape the conditions under which knowledge circulates. Open science therefore became an ethical and civic question, not merely an information-management procedure.

The Academy's broad disciplinary structure made open science both necessary and difficult. In some natural and technical sciences, large datasets, code, laboratory protocols, and computational workflows can be shared in structured repositories, although even here problems of proprietary methods, patentability, or sensitive information may arise. In environmental research, long-term monitoring data can be of great public value but may require careful documentation and quality control. In biomedical research, personal data and ethical constraints are central. In archaeology, opening precise site information can endanger heritage resources. In linguistics and social sciences, consent, anonymisation, and cultural sensitivity are crucial. In the humanities, digitised sources, editions, corpora, and bibliographies may be open, but copyright, archival restrictions, and interpretive context matter. The Academy therefore needed an open science policy flexible enough to respect disciplinary differences while still establishing common principles.

The humanities and social sciences have a particularly complex relationship with open access. Their research often appears in monographs, edited volumes, critical editions, dictionaries, catalogues, and national-language publications, not only in journal articles. Commercial open access models based on article processing charges may not fit these fields well. Book processing charges can be expensive, and the audience for Czech-language scholarship may include teachers, local institutions, cultural workers, and citizens as well as international scholars. Open access can greatly increase the public value of humanities research, but it must be implemented in ways that do not damage small scholarly publishers, national-language publishing, or specialised editorial work. For the Academy, this meant that open access could not be designed only around the publication practices of biomedical or physical sciences. It had to include the scholarly ecology of books, editions, archives, and cultural heritage.

Research data policies also changed the meaning of reproducibility. In experimental sciences, reproducibility is often associated with the ability to verify methods, repeat analyses, and inspect data. In humanities and social sciences, reproducibility may take different forms: access to sources, transparency of interpretation, documentation of coding decisions, openness of corpora, or clarity about archival selection. Open science therefore encouraged each field to articulate what verification and reuse mean in its own terms. This was important because the Academy's institutes could not all follow one uniform model. A molecular biology dataset, an astronomical observation, a sociological interview corpus, a medieval manuscript

edition, and a climate model output require different standards. The policy challenge was to establish shared commitments without flattening epistemic diversity.

Open science also intersected with research integrity. Data availability, transparent methods, open protocols, responsible authorship, and clear licensing can reduce the risk of error, irreproducibility, and questionable research practices. They also make it easier for other researchers to verify, criticise, reuse, or build upon published work. The Academy's Open Science Principles explicitly linked openness with higher quality, transparency, sustainability, and reproducibility of research (*Czech Academy of Sciences, 2024*). This connection is essential. Open science is not only about generosity towards readers; it is about the reliability of scientific knowledge. When data and methods are invisible, trust depends heavily on authority. When they are responsibly documented and accessible, trust can be supported by verification. Open science therefore strengthens the epistemic foundations of public research.

At the same time, openness can create new risks if it is implemented without care. Data may be misinterpreted when separated from context. Sensitive information may be exposed. Indigenous or local knowledge may be appropriated. Commercial actors may reuse public research without fair return. Researchers may be pressured to share data before they have had a reasonable opportunity to analyse it. Poorly documented datasets may become technically open but practically useless. Open science therefore requires governance, not just enthusiasm. The Academy's formula "as open as possible, as closed as necessary" responds to precisely this problem. It recognises that responsible openness includes protection, timing, explanation, and stewardship.

The economics of open access posed another difficulty. Traditional subscription models restrict readers, while many gold open access models shift costs to authors or institutions through article processing charges. This can create inequalities between well-funded and poorly funded researchers, disciplines, and countries. Transformative agreements, institutional publishing platforms, repositories, and diamond open access models all attempt to solve parts of this problem, but none is simple. For the Academy, the issue was not only how to make publications open, but how to do so sustainably and equitably. A public research institution must avoid replacing one barrier with another. If paywalls exclude readers, high publication fees can exclude authors. Open access policy therefore became linked to budgeting, library negotiation, institutional support, and national consortia.

The Academy's open science agenda also affected evaluation. If research assessment rewards only journal prestige or publication counts, researchers may have weak incentives to share data, software, negative results, protocols, or public-facing outputs. The Academy's research assessment reforms in the 2020s, especially its alignment with responsible assessment principles, therefore complemented open science. The CAS Open Science Principles explicitly noted that implementation of open science practices should be rewarded in the evaluation of research and professional activities of CAS institutes (*Czech Academy of Sciences, 2024*). This is important because cultural change requires incentives. Researchers will take open science seriously when it is recognised as part of good research practice, not treated as an optional administrative afterthought. Evaluation and open science are thus mutually connected.

Open science also changed the role of software. In many fields, research results depend on code, scripts, workflows, models, and computational environments. If these remain hidden, the published result may be difficult to verify or reuse. The Academy's Open Science Principles recommended that program code necessary for reusing or validating published data should,

where possible, be made available under an open-source licence in a public repository (*Czech Academy of Sciences, 2024*). This recommendation reflects the growing importance of computational research. Software is no longer a secondary technical tool. It is often part of the method itself. Making code available strengthens transparency and allows others to reproduce analyses, improve tools, or detect errors. Yet software sharing also requires documentation, licensing, maintenance, and sometimes protection of sensitive or proprietary elements.

Training became a central condition of implementation. Open science demands skills that many researchers were not formally taught: metadata creation, repository selection, data anonymisation, licensing, version control, persistent identifiers, data management plans, FAIR assessment, and rights retention. Senior researchers may have to change long-established habits, while early-career researchers may face expectations that are still unevenly supported. The Library of the CAS and its Open Science Department therefore play a pedagogical role as well as an administrative one. Tools such as the CAS FAIR Wizard for data management plans help make new requirements more manageable (*Czech Academy of Sciences, 2025*). Such support matters because open science cannot become part of research culture if it is experienced only as an external obligation. It must be taught as a set of practical competences.

The public dimension of open science is especially important for AV ČR because the Academy presents itself as conducting top research in the public interest. Public access to publications, datasets, educational materials, and expert outputs can strengthen the relationship between science and society. Open science can help teachers use current knowledge, journalists consult reliable sources, public bodies access evidence, enterprises develop innovations, and citizens understand research funded from public resources. It can also strengthen trust by showing that scientific institutions are willing to expose their methods and results to scrutiny. However, public access does not automatically produce public understanding. Open science must be accompanied by communication, explanation, and mediation. Raw data alone rarely speaks to society. The Academy's wider communication and public-engagement activities therefore remain essential.

The digital transformation of scholarly communication also raised questions of preservation. Digital publications, datasets, code, and repositories require long-term maintenance. Without preservation planning, open outputs may disappear, become unreadable, lose metadata, or remain accessible only in obsolete formats. Public research institutions therefore have responsibilities that extend beyond immediate publication. They must think about durable identifiers, archival standards, trusted repositories, file formats, metadata quality, and institutional memory. The Academy's long tradition of libraries, archives, collections, and documentation gives it a historical sensitivity to preservation. Open science translates this older responsibility into the digital age. The problem is no longer only how to preserve books and manuscripts, but how to preserve complex digital research objects.

The relationship between open science and intellectual property required careful balance. The Academy's institutes sometimes produce knowledge with potential for patents, technologies, applied contracts, software, or collaboration with industry. Premature openness can undermine legitimate protection or commercialisation. Conversely, excessive secrecy can limit public value and scientific verification. The Open Science Principles therefore explicitly recognise the need to protect intellectual property while encouraging openness (*Czech Academy of Sciences, 2024*). This balance is especially important in fields such as biotechnology, materials science, energy, informatics, and medical research. The Academy's

task is not to choose between open science and innovation. It is to develop governance that allows both public access and responsible protection where justified.

Open science also interacts with international cooperation. European projects increasingly require shared repositories, data management plans, open access publications, common standards, and interoperable metadata. International consortia cannot function well if each partner manages data in incompatible ways. For Academy institutes, open science therefore became part of the technical foundation of cooperation. FAIR data makes collaboration easier because partners can find, understand, combine, and reuse each other's results. Open access publications increase the visibility of Czech research in international networks. Open-source code can support joint method development. Thus, open science strengthens the Academy's integration into the European Research Area not only normatively but practically.

The Academy's open science policies also reflect a broader transformation of academic authority. In older scholarly cultures, authority often rested on institutional prestige, individual reputation, and publication in recognised venues. These remain important, but open science adds another dimension: the credibility of processes. A result becomes more trustworthy when its data, methods, code, and supporting materials can be inspected under appropriate conditions. This does not eliminate the need for expertise; open data without expertise can lead to misunderstanding. But it changes the relationship between expertise and transparency. The Academy's public authority in the 2020s increasingly depends on both high-level knowledge and the openness of the processes through which that knowledge is produced.

The implementation of open science will remain uneven. Some institutes and disciplines are better prepared than others. Some have well-established data standards and repositories; others are still developing them. Some researchers welcome open science as an improvement in collaboration and trust; others fear administrative burden, loss of control, misuse of data, or inadequate recognition. These tensions are normal in a major cultural transition. The Academy's role is to provide common principles while allowing field-specific pathways. It must support early adopters, help hesitant institutes, avoid one-size-fits-all rules, and ensure that openness does not become merely formal compliance. Successful implementation depends on trust, training, infrastructure, incentives, and leadership.

By the mid-2020s, open science had become part of the Academy's broader institutional self-definition. It connected with research evaluation, European integration, digital libraries, scholarly communication, public accountability, research integrity, and career development. It also reflected the Academy's historical movement from a closed and politically supervised system to an autonomous, transparent, and internationally embedded research organisation. The contrast with the socialist period is striking. Under state socialism, information circulation was shaped by ideology, hierarchy, restricted mobility, and unequal access to foreign knowledge. In the contemporary Academy, the institutional aim is the widest possible responsible dissemination of research outputs. This does not mean that all obstacles have disappeared. It means that openness has become a recognised norm against which institutional practice can be judged.

Thus, open access and research data policies represent a decisive stage in the modernisation of the Czech Academy of Sciences. They extend the post-1989 ideals of freedom, autonomy, and international integration into the digital and infrastructural conditions of contemporary research. The Academy's transition from the 2010 Open Access Policy to the 2024 Open Science Principles shows a movement from publication access towards the responsible

openness of publications, data, software, methods, and research processes. This transformation has been shaped by Czech national policy, Horizon Europe requirements, EOSC, FAIR principles, UNESCO recommendations, and the Academy's own public mission. It creates new opportunities for transparency, reproducibility, collaboration, education, and trust, but it also brings challenges of cost, data protection, intellectual property, disciplinary difference, and administrative burden. The Academy's achievement lies in recognising that open science is not an external technical demand but a new form of public responsibility. In this sense, open access and research data policies have become part of the institutional culture through which AV ČR defines itself as a modern European academy of sciences.

2. Digital Libraries, Archives, and Scholarly Communication

Digital libraries, archives, and scholarly communication form one of the most important infrastructures of the modern Czech Academy of Sciences. They are not only technical services attached to research institutes. They are the institutional memory, public interface, and communicative nervous system of the Academy. Since 1993, AV ČR has had to define itself as a modern public research organisation capable of producing new knowledge, preserving older knowledge, making results visible, and connecting its scholarly output with Czech society and international research communities. Digitalisation gave this task a new material form. The Academy's libraries, archives, repositories, catalogues, journals, and digital platforms became instruments through which continuity and openness could be held together. They preserved the Academy's historical inheritance while also creating new channels for dissemination, reuse, evaluation, and public access.

The transformation of scholarly communication after 1989 should be understood against the background of the previous regime's restricted circulation of knowledge. In the socialist period, scholarly communication was shaped by ideological supervision, limited access to foreign literature, controlled international exchange, and uneven availability of journals and databases. After the Velvet Revolution, the Academy's international reopening required not only travel and cooperation, but also informational reconstruction. Researchers needed access to contemporary publications, foreign databases, digital catalogues, and new channels of publication. Libraries therefore became strategic institutions in the post-socialist modernisation of science. They were not passive storehouses of books. They were mediators between the Academy's institutes and the rapidly changing global information environment.

The Library of the Czech Academy of Sciences became central to this transformation. Its role expanded from traditional library services towards digital infrastructure, electronic information resources, open access support, bibliometrics, institutional repositories, digitisation, and research communication. This expansion reflects a broader European and global change in research libraries. The modern research library manages not only printed collections, but also licences, metadata, digital preservation, repositories, scholarly journals, persistent identifiers, and data services. In the Academy's case, this role is especially important because the institution is not a single university campus but a dispersed network of specialised institutes. The Library helps connect these institutes through common systems of access, publication evidence, digital preservation, and scholarly visibility. It therefore functions as one of the integrative institutions of AV ČR.

The Digital Library of the Czech Academy of Sciences is perhaps the clearest example of this integrative role. It contains digitised periodicals and monographs produced by institutes of the Academy and their predecessors, while also including born-digital publications such as newer articles and electronic monographs published by CAS institutions (*Library of the Czech Academy of Sciences, n.d.*). This combination of digitised heritage and born-digital scholarship is historically significant. It means that the Digital Library is not merely a retrospective archive of old materials. It is also a platform for contemporary scholarly communication. The long-term aim of making publications of CAS units accessible through the digital library expresses a particular understanding of institutional memory. The Academy's intellectual production should not disappear into scattered shelves, obsolete formats, inaccessible journals, or departmental websites. It should be preserved as part of a shared scholarly corpus.

The Digital Library also gives visible form to the Academy's layered history. Publications of present CAS institutes sit alongside works produced by their predecessors, including institutes of ČSAV and earlier learned organisations. This matters for the institutional history of the Academy because many research traditions survived political rupture, legal transformation, and organisational restructuring. A digitised periodical, monograph, or report may reveal continuities that administrative documents alone cannot show. It may trace the evolution of a discipline, a school of thought, a research programme, or a scientific community across regimes. Digital access therefore turns the Academy's history into an active research resource. It allows scholars to study not only the Academy as an institution, but also the intellectual output through which that institution justified itself over time.

The access model of the Digital Library reveals the complexity of openness in practice. Some documents can be read, downloaded, and printed publicly because they are out of copyright or made available by licence. Other documents are accessible after login under arrangements for works unavailable on the market, while still protected by copyright. Some materials can only be consulted within the library study room because of licensing restrictions (*Library of the Czech Academy of Sciences, n.d.*). This layered access structure shows that digitalisation does not automatically mean unrestricted openness. It must operate within copyright law, licence agreements, institutional responsibilities, and the rights of authors and publishers. The Academy's digital communication therefore rests on a careful balance between public access and legal responsibility.

The involvement of the Digital Library of the CAS in the Czech Digital Library places the Academy within the national system of digital cultural and scholarly infrastructure. The Czech Digital Library acts as a national aggregator of digital libraries operated in the Kramerius system and provides a common access point for digitised documents from participating institutions (*National Library of the Czech Republic, n.d.*). Through this system, the Academy's digitised materials enter a broader Czech information ecosystem and, through aggregation channels such as Europeana, can become visible within the European cultural heritage space (*Library of the Czech Academy of Sciences, n.d.*). This is a powerful example of how national and European infrastructures intersect. The Academy's digital heritage is not isolated behind institutional walls. It becomes part of a wider network of memory institutions, libraries, and digital humanities resources.

The Kramerius system is particularly important in this context. It is an open-source digital library system used by numerous institutions in the Czech Republic and Slovakia, and the Library of the Academy of Sciences has played a major role in its development and coordination

(*National Library of the Czech Republic, n.d.; *Kramerius, n.d.*). Kramerius represents more than software. It is a technological form of cooperation among libraries and memory institutions. It supports the presentation and management of digitised books, periodicals, maps, sheet music, historical prints, and born-digital documents. For AV ČR, participation in and development of such infrastructure demonstrates that the Academy contributes not only content but also technical solutions to the public knowledge environment. Digital scholarly communication therefore includes software, standards, and interoperability, not only texts.

The Academy's digitisation activities also strengthen preservation. Printed books, periodicals, reports, and rare materials are vulnerable to physical degradation, loss, dispersal, or restricted access. Digital copies cannot replace the originals, especially where material features matter, but they can reduce handling, broaden access, and create backup forms of preservation. The Digitisation Centre of the Library focuses especially on journals and monographs published by the Academy and makes the scanned documents available through the Digital Library (*Library of the Czech Academy of Sciences, n.d.*). This work converts a vulnerable and dispersed printed heritage into a searchable and more accessible digital corpus. It also supports historical research on the Academy itself, since institutional publications are among the most important sources for reconstructing scientific priorities, terminology, networks, and self-representation.

The mandatory submission of electronic publications issued by CAS departments to the Library gives digital preservation an institutional basis. This obligation ensures that electronic publications do not remain only on temporary project websites or local institute servers. It creates a pathway for collecting, archiving, and making available valuable scientific materials for future researchers and the public (*Library of the Czech Academy of Sciences, n.d.*). This is especially important in the digital age because born-digital materials are often more fragile than printed books. Websites disappear, formats become obsolete, and local files can be lost during organisational changes. A public research academy must therefore treat digital preservation as a core responsibility. The digital archive becomes the contemporary equivalent of the institutional shelf, but with more complex technical and legal requirements.

The AS Journals platform adds another dimension to the Academy's scholarly communication. It provides presentation and access to scientific periodicals published by the Academy of Sciences in open access mode, offering separate websites for journals and full-text browsing of journal content (*Library of the Czech Academy of Sciences, n.d.*). This platform is important because scholarly journals remain one of the main forms through which research communities organise communication, peer review, debate, and disciplinary identity. For CAS institutes, journals are also instruments of national and international scholarly presence. Many Academy journals operate in fields where Czech-language or Central European scholarship remains important, especially in the humanities and social sciences. AS Journals therefore supports both openness and disciplinary continuity.

The significance of AS Journals is particularly visible in fields where commercial publishing models do not fully serve scholarly needs. Many humanities and social-science journals have modest budgets, specialised audiences, multilingual traditions, and strong links to national scholarly communities. Open access through an institutional platform can protect such journals from both paywalls and excessive author charges. It can also strengthen editorial independence, public availability, and long-term archiving. In this respect, the Academy's journal platform corresponds to the logic of diamond or institutionally supported open access,

where access is free for readers and publication is not necessarily financed through high article processing charges. This model is especially valuable for small-language scholarship. It allows Czech and Central European research to remain visible without being forced entirely into commercial international publishing circuits.

The ASEP system represents another pillar of scholarly communication within AV ČR. Originally connected with the evidence of publication activity, ASEP developed into a crucial institutional infrastructure for recording, presenting, linking, and preserving research outputs. Its data repository stores data files with metadata created by authors from CAS institutes, enables versioning, links data with bibliographic records, and is registered in the re3data registry of research data repositories (*Library of the Czech Academy of Sciences, n.d.*). This development shows how publication evidence, repositories, and research data policy have converged. The institutional record of research is no longer limited to bibliographic descriptions of articles and books. It now includes datasets, persistent identifiers, licences, and links between outputs and underlying materials. Scholarly communication has become more complex, but also more transparent.

ASEP is also important for evaluation. Research assessment requires reliable information about publications, datasets, affiliations, outputs, and institutional activity. Without a common evidence system, evaluation would depend on fragmented local records or commercial databases that do not capture all fields equally. ASEP helps the Academy maintain its own record of research production across disciplines. This is especially important for humanities and social sciences, where monographs, edited volumes, critical editions, and Czech-language outputs may be poorly represented in international citation databases. By maintaining its own evidence infrastructure, the Academy preserves the ability to see and evaluate its research in a more field-sensitive way. Digital scholarly communication therefore supports both openness and institutional self-knowledge.

The relationship between repositories and research data also changes the meaning of authorship and responsibility. When researchers deposit datasets, code, metadata, or supporting resources, they make part of the research process visible beyond the final publication. This increases the responsibility of authors to document their work carefully, choose appropriate licences, protect sensitive data, and ensure that materials can be reused. It also changes the role of readers, who may become users, validators, re-analysts, or collaborators. The Academy's data repository therefore supports a more interactive model of scholarly communication. Research outputs are no longer only finished texts moving from author to reader. They are connected objects within a digital knowledge environment.

The Masaryk Institute and Archives of the Czech Academy of Sciences represents the archival dimension of this infrastructure. It manages extensive archival and library holdings and is responsible for records of the Academy of Sciences, archival fonds of older scientific institutions, and personal fonds of scientists working in the Czech lands (*Masaryk Institute and Archives of the CAS, n.d.*). It also provides pre-archival care and shredding supervision within the Academy. This role is vital because an institution as complex as AV ČR continuously produces records of governance, research, personnel, correspondence, projects, evaluations, and institutional memory. Archives ensure that these records are preserved, described, and made available under appropriate conditions. Without such archival work, the history of the Academy would fragment into anecdote and administrative residue.

The fonds of ČSAV and AV ČR preserved by the Masaryk Institute and Archives are especially significant for the institutional history of Czech science. They include records of bodies, units, and institutes of the Czechoslovak Academy of Sciences from 1952 to 1992 and of the Czech Academy of Sciences since 1993 (*Masaryk Institute and Archives of the CAS, n.d.*). This continuity of archival preservation allows researchers to trace institutional change across the socialist and post-socialist periods. It makes possible the study of restructuring, disciplinary development, leadership, personnel policy, international cooperation, evaluation, and the changing relationship between science and the state. The archive therefore performs not only a bureaucratic function but also a historiographical one. It supplies the sources through which the Academy can be critically studied.

The digital availability of archival guides and databases adds a further layer to this function. Online guides to fonds and collections make archival knowledge discoverable beyond the reading room and help researchers identify relevant materials before visiting the archive (*Masaryk Institute and Archives of the CAS, n.d.*). This is a major change in archival culture. Earlier, access often depended heavily on local knowledge, personal contact, or printed finding aids. Digital catalogues and databases make archival research more transparent and efficient. They also allow international researchers to discover Czech scientific archives more easily. Digital archival communication therefore supports both national scholarship and internationalisation.

The archival dimension is especially important for a history of the Academy because the institution has repeatedly been redefined by political change. The socialist foundation of ČSAV, the reforms of the 1960s, the purges of normalisation, the crisis of 1989, the birth of AV ČR in 1993, and later evaluation and Europeanisation all generated institutional records. These records are not neutral. They contain traces of power, language, hierarchy, conflict, ambition, and self-justification. The archive preserves them, but also makes them available for critical interpretation. This is why digital archives and archival databases should not be treated only as service tools. They are instruments of institutional transparency and historical accountability.

The Library's collection of manuscripts, early printed books, and rare works connects the Academy's modern research communication with deeper cultural memory. The collection includes printed books from the 16th to 19th centuries, incunabula, manuscripts, and materials inherited or acquired from older learned and cultural institutions (*Library of the Czech Academy of Sciences, n.d.*). Its selective digitisation and presentation through digital platforms show how the Academy participates in the preservation of Czech and European book culture. This is not unrelated to contemporary science. Historical collections are research infrastructures for codicology, bibliography, intellectual history, philology, religious history, art history, and cultural heritage studies. Their digital accessibility broadens the community of potential users and connects rare materials with new methods of digital humanities.

Knihověda.cz offers another example of the Academy's contribution to digital humanities and scholarly communication. The portal provides access to bibliographic resources, interpretive texts, and research tools for Czech book culture, including a comprehensive bibliographic database of Bohemian printed books, manuscripts, and modern literature, and it links older retrospective bibliographical traditions such as Knihopis and the Bibliography of Foreign-Language Printed Bohemica up to 1800 (*Library of the Czech Academy of Sciences, n.d.*). This kind of resource shows that digital scholarly communication is not limited to digitising pages. It also involves creating structured knowledge environments, databases, maps,

encyclopaedias, and analytical tools. The database becomes a research argument in its own right. It organises a field and enables new questions.

Digital humanities tools developed or supported within the Academy illustrate the changing relationship between libraries, archives, and research. Traditional divisions between librarian, archivist, editor, historian, philologist, programmer, and data specialist become less rigid in digital projects. A digital bibliography, corpus, map, or repository requires scholarly expertise, metadata standards, software development, user-interface design, preservation planning, and sometimes machine-learning tools. The Library of the CAS has explicitly described its applied research in terms of software tools and systems for digitising and managing digital documents, including open-source solutions and tools for digital humanities (*Library of the Czech Academy of Sciences, n.d.*). This shows that the Academy's information infrastructure is itself a site of research and innovation. Libraries do not merely support science; they can produce research technologies.

Electronic information resources and licensing also changed the Academy's scholarly communication. Access to international journals, databases, e-books, and citation indexes is essential for research competitiveness. The CzechELib consortium and related national arrangements for electronic information resources helped centralise licensing and improve access for Czech research and educational institutions (*CzechELib, n.d.*). For CAS institutes, such access is a condition of international participation. A researcher cannot contribute effectively to global debates without current literature. At the same time, the economics of licensed databases and commercial publishing created new tensions. Libraries had to negotiate access while supporting open access alternatives. Scholarly communication therefore became a field of economic and political negotiation, not simply intellectual exchange.

The coexistence of subscription access, open access platforms, institutional repositories, and digital libraries reflects the transitional character of contemporary scholarly communication. The Academy does not operate in a fully open knowledge economy. Researchers still rely on subscription databases, commercial journals, publisher platforms, and licensed resources. At the same time, they are increasingly expected to deposit publications, share data, publish open access, and support public availability. This hybrid system is administratively complex and sometimes contradictory. Libraries must support access under both old and new models. Researchers must navigate publisher rules, funder requirements, institutional policies, and evaluation expectations. The modernisation of scholarly communication therefore involves managing transition rather than simply declaring openness.

Digital scholarly communication also affects the visibility of Czech research. Publications in small languages, institute series, national journals, and specialised editions can remain invisible if they are not indexed, digitised, described, and made accessible. Platforms such as the Digital Library, AS Journals, ASEP, and Knihověda help counter this invisibility. They allow Czech research outputs to be found by international users, included in aggregators, linked to identifiers, and preserved for long-term consultation. This is particularly important for humanities and social sciences, where national-language scholarship often carries high cultural value but may be marginal in global commercial databases. Digital infrastructure therefore helps defend scholarly diversity. It makes smaller research cultures more visible without forcing them entirely into English-language commercial publication systems.

At the same time, digital visibility introduces new evaluative pressures. When outputs become easier to count, index, harvest, and compare, they can also become easier to reduce to indicators. Repositories and bibliographic systems support evaluation, but they can also feed metric-driven cultures if used without interpretation. The Academy's broader reform of research assessment is therefore relevant here. Digital scholarly communication should make research more visible and reusable, not merely more countable. A monograph, database, edition, digital map, or archival guide may have value that is not captured by citation metrics. The Academy's task is to connect digital evidence systems with informed peer review and field-sensitive assessment. Otherwise, infrastructure designed for openness could unintentionally strengthen crude quantification.

Digital communication also changes the relationship between the Academy and the public. A digitised journal, an online archival guide, an open database, or a searchable digital collection can be used by teachers, students, journalists, local historians, policymakers, and interested citizens. This expands the audience of the Academy beyond professional researchers. It also makes public accountability more concrete. A citizen can see research outputs, explore older publications, consult historical materials, or access open journals without passing through institutional gates. However, wider access does not automatically produce understanding. Digital platforms must be accompanied by explanation, navigation, metadata, translation, educational materials, and public communication. The Academy's digital infrastructure therefore works best when connected with science communication and outreach.

The COVID-19 pandemic highlighted the importance of digital libraries, repositories, and electronic communication. When physical access to libraries, archives, laboratories, conferences, and reading rooms was restricted, digital access became not merely convenient but essential. Researchers depended on electronic resources, remote databases, digitised materials, online meetings, and repository access. The pandemic did not create digital scholarly communication, but it accelerated recognition of its importance. It also revealed inequalities: not all materials were digitised, not all disciplines could shift online equally, and not all users had the same access to licensed resources. For the Academy, the pandemic confirmed that digital infrastructure is part of institutional resilience. A modern research organisation must be able to preserve communication under crisis conditions.

Digital archives and libraries also raise questions of authenticity and context. A digitised image of a manuscript or printed book is immensely useful, but it does not replace the material object. Binding, paper, marginalia, watermarks, provenance marks, damage, and physical scale may all matter. Similarly, digital archival descriptions can guide research, but archival interpretation still requires understanding of provenance, arrangement, institutional history, and record creation. Digital access therefore should not be confused with complete transparency. It opens doors but does not remove the need for expertise. The Academy's libraries and archives must therefore combine accessibility with scholarly mediation. Digitalisation should deepen, not flatten, historical and material understanding.

Long-term preservation of digital scholarly communication remains one of the most serious challenges. Digital objects require maintenance, migration, metadata, persistent identifiers, backup, format monitoring, and institutional commitment. Open access journals can disappear without preservation systems, and project websites can vanish after funding ends (*Laakso, Matthias, & Jahn, 2021*). The Academy's repository, digital library, and mandatory submission systems respond to this risk by embedding digital outputs in institutional

infrastructure. This is crucial because research communication must outlast individual projects and temporary technologies. AV ČR's responsibility is not only to disseminate knowledge now, but also to preserve it for future scholarship. Digital modernisation therefore has a temporal depth similar to traditional archival work.

The digital transformation of scholarly communication also produced new professional roles. Librarians, archivists, data stewards, repository managers, digitisation specialists, metadata experts, copyright advisers, software developers, bibliometric analysts, and open science officers became increasingly important. Their work is often less visible than that of researchers, but it is essential for the functioning of modern science. The Academy's institutes cannot participate effectively in open science, European projects, data sharing, or digital preservation without such expertise. This changes the human structure of research institutions. Scientific excellence depends not only on principal investigators and research teams, but also on professional infrastructures of knowledge management. The modern Academy is therefore a more complex organisation than the older image of scholars working within self-contained institutes suggests.

Digital scholarly communication also strengthens interdisciplinary work. Databases, corpora, repositories, digital maps, and linked metadata can connect fields that previously worked separately. A historical source database may be used by historians, linguists, computer scientists, educators, and cultural heritage professionals. Environmental data may be relevant to ecologists, climatologists, geographers, policymakers, and social scientists. Digital platforms create shared objects around which interdisciplinary cooperation can form. The Academy's broad disciplinary structure makes it particularly well suited to such work. Digital libraries and repositories can become meeting points between the humanities, social sciences, natural sciences, and technical fields. They therefore support not only access but also new forms of research collaboration.

The international dimension of digital scholarly communication is equally important. Digital platforms make Czech materials discoverable abroad, while international standards make Czech repositories interoperable with European systems. Aggregation through the Czech Digital Library and Europeana places CAS materials within wider European cultural heritage networks. Registration of data repositories in international registries, use of persistent identifiers, and compliance with FAIR principles help integrate Academy outputs into global research infrastructures. This means that digital communication is one of the practical mechanisms of the Academy's European Research Area participation. Internationalisation no longer depends only on physical mobility or project consortia. It also depends on whether digital objects can be found, cited, harvested, reused, and preserved across borders.

Digital scholarly communication also has a democratic dimension. It supports a more open relationship between science and society by reducing barriers to knowledge. Yet it also creates responsibilities concerning misinformation, misuse, and interpretation. Public access to scientific materials does not guarantee that they will be used correctly. Data can be taken out of context; archival documents can be politicised; preliminary findings can be misrepresented; historical sources can be read without methodological caution. The Academy therefore has to combine openness with explanation and expertise. Digital communication makes knowledge more available, but it also increases the need for responsible mediation. The Academy's authority in the public sphere depends partly on how it manages this balance.

By the mid-2020s, digital libraries, archives, repositories, and journal platforms had become essential to AV ČR's institutional identity. They supported open science, research evaluation, historical memory, public access, international visibility, digital humanities, and long-term preservation. They also showed that the Academy's modernisation was not confined to laboratories, grants, or evaluation panels. It extended into the infrastructures through which knowledge is recorded, organised, shared, and remembered. The Library of the CAS and the Masaryk Institute and Archives therefore stand as central institutions within the modern Academy. They make visible the fact that scientific modernisation is also documentary, archival, bibliographic, and communicative. Knowledge must be produced, but it must also be preserved and transmitted.

Thus, digital libraries, archives, and scholarly communication transformed the Czech Academy of Sciences into a more open, connected, and historically self-aware research institution. The Digital Library of the CAS preserved and disseminated publications of Academy institutes and their predecessors; AS Journals supported open access to Academy periodicals; ASEP connected publication evidence, repositories, data, and evaluation; and the Masaryk Institute and Archives preserved the institutional memory of ČSAV and AV ČR. These infrastructures linked the Academy's national scholarly responsibility with European and global standards of digital access, interoperability, and preservation. They also revealed new tensions involving copyright, licensing, digital fragility, metricisation, disciplinary diversity, and public interpretation. The deeper significance of this transformation lies in the fact that the Academy's history and its present research activity became increasingly accessible as organised digital knowledge. In this sense, digital scholarly communication did not merely support the Academy's modernisation. It became one of the forms through which that modernisation was realised.

3. Research Integrity, Transparency, and Public Accountability

Research integrity, transparency, and public accountability became central elements of the Czech Academy of Sciences' modernisation because the legitimacy of public research after 1989 could no longer be based on institutional authority alone. The Academy had to show not only that it produced high-quality research, but also that this research was conducted honestly, responsibly, openly, and in a manner compatible with democratic public life. In the socialist period, the problem of integrity had often been obscured by ideological loyalty, political supervision, and administrative hierarchy. After the Velvet Revolution, the Academy's claim to autonomy required a different foundation. Scientific freedom had to be joined with responsibility, and public funding had to be joined with trust. This is why integrity and accountability cannot be treated as secondary ethical appendices to the history of AV ČR. They are part of the institutional architecture through which the Academy moved from the inherited logic of state-controlled science to the norms of a modern European research organisation.

The meaning of research integrity in the Academy is broader than the avoidance of misconduct. It includes honesty in designing, conducting, reviewing, and communicating research; reliability in methods and records; respect for colleagues, students, research participants, and the public; and accountability for the consequences of scholarly work. This wider understanding corresponds to the European Code of Conduct for Research Integrity, which defines reliability, honesty, respect, and accountability as fundamental principles of good research practice (*ALLEA, 2023*). For AV ČR, these principles are especially important because

the Academy covers a broad spectrum of disciplines. Integrity in molecular biology, archaeology, mathematics, social research, philosophy, environmental monitoring, and digital humanities cannot be implemented through identical routines. Yet all these fields require a common moral grammar: careful work, truthful reporting, respect for evidence, fair attribution, and willingness to be scrutinised.

The Code of Ethics for Researchers of the Czech Academy of Sciences provides one of the basic institutional expressions of this grammar. It formulates general principles of academic conduct and includes freedom of research, fairness, equal opportunities, responsibility, honesty, diligence, trust, and respect for others among the fundamental values of the academic environment (*Czech Academy of Sciences, n.d.*). These principles are significant because they connect individual behaviour with institutional culture. A research organisation cannot maintain integrity only by punishing the most obvious violations. It must cultivate habits of accuracy, mutual respect, responsible authorship, transparent supervision, fair evaluation, and serious treatment of evidence. The Code therefore functions not only as a disciplinary document but as a statement about what kind of scholarly community the Academy wishes to be.

The principle of freedom of research deserves particular attention in the Czech context. After decades in which ideology could shape research topics, institutional careers, publication opportunities, and permissible interpretations, freedom became one of the most important values of post-1989 science. Yet freedom without integrity is fragile. If research freedom is used to justify carelessness, plagiarism, fabrication, harassment, or manipulation, it destroys the public trust on which autonomy depends. The Academy's ethical framework therefore links freedom to responsibility. Researchers must be free from political command, but they must also be accountable to evidence, method, colleagues, students, research participants, and society. This balance is one of the central achievements of democratic scientific culture.

The institutionalisation of research integrity is visible in the role of the Scientific Integrity Committee of the CAS. The Statutes of the Academy provide that the Council for Sciences establishes a committee dealing with general questions of ethics of scientific work and with significant breaches of this ethics (*Czech Academy of Sciences, n.d.*). This mechanism is important because integrity cannot depend only on informal reputation or local institute culture. A central committee provides a point of reference for difficult cases, cross-institute issues, and general ethical questions affecting the Academy as a whole. It also symbolises the fact that research integrity is not only a private matter between individuals. It is an institutional responsibility. The Academy must have structures capable of receiving, interpreting, and responding to concerns about scientific conduct.

The existence of such a committee also reflects the evolution of accountability inside the Academy. In the immediate post-socialist period, accountability was strongly connected with institutional restructuring, personnel review, and the rejection of ideological control. By the 2000s and 2010s, it became more connected with evaluation, funding, open access, and international standards. In the 2020s, it increasingly includes research culture, safe working environments, equality, respectful behaviour, and the protection of those who report problems. The creation of the CAS ombudsperson position in 2025 belongs to this wider development. Its purpose is to protect people working in the CAS community from undesirable conduct and to contribute to a safe, fair, and respectful working environment (*Czech Academy*

of Sciences, 2025). This broadens institutional integrity from research outputs to working relations.

The ombudsperson role is important because misconduct and lack of integrity are not limited to falsified data or plagiarism. A research institution may produce excellent publications while tolerating bullying, abuse of power, discrimination, exploitative supervision, authorship pressure, or retaliation against whistle-blowers. Such practices damage science because they distort careers, silence criticism, weaken trust, and make research environments unsafe. Modern research integrity therefore includes questions of workplace culture and leadership. The Academy's Code of Conduct and ombudsperson mechanism indicate that AV ČR increasingly recognises this connection. A modern academy cannot defend intellectual excellence while ignoring the social conditions under which researchers work. Integrity is cultural before it is procedural.

Transparency is the second major element of this modern research culture. It has several meanings in the Academy's context. It means openness of research outputs through open access and data policies. It means publication of annual reports, institutional documents, evaluation materials, strategies, and legal regulations. It means clear rules for governance, funding, assessment, and ethical procedures. It also means public communication about the Academy's activities, achievements, controversies, and responsibilities. Transparency therefore connects the internal world of science with the external world of society. It allows the public to see how a publicly funded research institution functions and why it matters.

The Academy's Open Science Principles make the link between transparency and integrity explicit. They describe open science as a path to higher quality, transparency, sustainability, and reproducibility of research (*Czech Academy of Sciences, 2024*). This connection is crucial. Transparency is not merely a public-relations value. In science, transparency improves the conditions for verification, criticism, reuse, and correction. Open access to publications, responsible data management, FAIR principles, open software where possible, and trusted repositories all help make research more inspectable and reusable. They reduce the distance between claim and evidence. In this sense, open science is one of the practical instruments of research integrity.

Yet transparency must be responsible. The Academy's principle "as open as possible, as closed as necessary" recognises that openness has ethical, legal, and disciplinary limits (*Czech Academy of Sciences, 2024*). Personal data, sensitive health information, endangered species locations, archaeological sites, cultural heritage materials, intellectual property, security-relevant research, and confidential interviews cannot always be fully opened. Responsible transparency therefore requires judgement, not mechanical disclosure. This is important because careless openness can harm individuals, communities, heritage resources, or future research. A mature institution must be able to justify both openness and closure. Transparency becomes credible when it is governed by clear reasons rather than convenience.

Public accountability is closely linked with the Academy's financial and legal status. AV ČR is a public institution supported from the state budget and operating through institutes that conduct research across a wide range of fields. This position gives it autonomy, but also creates obligations. The Academy must report on its activities, explain its results, defend its use of public funds, and demonstrate its contribution to Czech society. Annual reports are therefore not merely administrative documents. They are instruments of public accountability.

They record research results, institutional developments, financial information, public communication, international cooperation, and strategic priorities. Through them, the Academy presents itself to the state, the scientific community, and the public.

The regular publication of annual reports has a broader historical significance. Under state socialism, institutional reporting existed, but it was embedded in a political-administrative system in which public accountability was limited and ideological self-presentation was often expected. In the democratic period, annual reports became part of a different accountability regime. They are not simply reports upwards to a party-state hierarchy; they are public documents that help society understand the work of the Academy. This does not mean that reports are neutral or complete. They still select, organise, and present information. But their public character changes the relationship between the Academy and society. The institution must make itself legible.

Evaluation reports are another form of transparency and accountability. The Academy's institute evaluations, especially the detailed assessments developed in the 2010s and 2020s, provide structured information about the quality, strategy, strengths, and weaknesses of research organisations. Their public or semi-public availability shows that the Academy does not merely ask society for trust; it submits itself to expert judgement. This is important because public accountability in science cannot be reduced to political control. The public cannot directly evaluate every scientific result. It needs credible procedures through which experts assess quality while remaining themselves accountable. Evaluation therefore mediates between scientific autonomy and public responsibility.

The reform of research assessment in the 2020s strengthened this mediation. By aligning with CoARA principles and emphasising qualitative peer review, diversity of research contributions, and responsible use of indicators, the Academy sought to make evaluation more intelligent and less mechanically metric-driven (*Coalition for Advancing Research Assessment, 2022*; *Czech Academy of Sciences, 2024*). This is directly connected with integrity. A poorly designed evaluation system can create incentives for questionable research practices, excessive publication pressure, superficial output production, and strategic metric gaming. A responsible evaluation system can support deeper quality, fairness, and long-term research. Assessment reform is therefore not only a management issue. It is part of the ethical environment of science.

The European Code of Conduct for Research Integrity, made available in Czech by the Academy, further connected AV ČR with European norms of responsible research (*Czech Academy of Sciences, 2024*). This translation and dissemination matter because research integrity depends on shared understanding. Scientists need common concepts to discuss authorship, data practices, supervision, peer review, conflicts of interest, collaborative work, and misconduct. The European Code also reflects new issues arising from open science, data-intensive research, research assessment, and changing research culture (*ALLEA, 2023*). By placing this document within the Czech academic environment, the Academy helped align national research culture with European standards while making them accessible to Czech-speaking researchers and institutions.

Research integrity is also deeply connected with authorship. Modern research is often collaborative, multi-institutional, international, and interdisciplinary. This creates possibilities for confusion or abuse: honorary authorship, ghost authorship, unjust exclusion of junior researchers, unequal credit in team science, and disputes over contribution. The Academy's

ethical culture must therefore support fair attribution and responsible authorship practices. This is especially important for early-career researchers, who may lack power in hierarchical teams. Authorship is not only a technical bibliographic question. It determines career opportunities, reputation, grant competitiveness, and professional identity. A transparent authorship culture is therefore one of the everyday foundations of integrity.

Data integrity is another major issue. Fabrication, falsification, selective reporting, poor documentation, irresponsible image manipulation, and unreliable data storage can damage entire research fields. Open data policies can reduce some risks, but only if data are well managed, documented, preserved, and ethically shared. The FAIR principles and data management plans discussed in the previous section therefore have ethical significance. They support traceability, verification, and reuse. For the Academy, which includes experimental, observational, computational, archival, and interpretive disciplines, data integrity must be understood broadly. It concerns laboratory notebooks, code, survey data, interviews, field observations, archival records, images, corpora, and digital objects.

Peer review is also part of research integrity. Reviewers must act fairly, confidentially, competently, and without conflicts of interest. This applies to journal review, grant review, institute evaluation, promotion procedures, and internal assessment. Because AV ČR relies heavily on peer review in both research evaluation and funding competition, the integrity of peer review is essential to institutional trust. A biased or careless review can affect careers, projects, and institute resources. Conversely, serious peer review strengthens quality and accountability. The Academy's modern evaluation culture therefore depends not only on methodology but on ethical conduct by reviewers and panels. Integrity enters the governance of science through the judgement of peers.

Conflicts of interest form another important area. In a relatively small national research system, personal, institutional, and disciplinary connections are often dense. Researchers may evaluate colleagues, former students, collaborators, competitors, or institutes with which they have indirect relations. Such situations are not always avoidable, but they must be disclosed and managed. Transparency about conflicts of interest protects both the evaluated party and the evaluator. It also protects the institution from suspicion. The Academy's increasing use of international reviewers and formal procedures can reduce local bias, but it cannot eliminate the need for conflict-of-interest awareness. Public accountability requires that decisions be not only fair but visibly fair.

The relationship between research integrity and international cooperation became more complex in the 2020s. European projects, global collaborations, data sharing, and mobility create cross-border ethical questions. Partners may operate under different legal systems, authorship norms, data standards, or political conditions. Cooperation with institutions in authoritarian contexts may raise questions of academic freedom, surveillance, dual-use technologies, or misuse of research. The Academy's participation in European Research Area debates therefore also involves responsibility for international partnership. Openness remains a central scientific value, but it must be combined with awareness of risk. Integrity in international cooperation requires due diligence, transparent agreements, and respect for both scientific freedom and ethical boundaries.

The Russian invasion of Ukraine in 2022 sharpened the ethical dimension of public accountability. The Academy publicly supported Ukrainian scientists and created fellowship support for researchers whose work was endangered by war or persecution (*Czech Academy*

of Sciences, 2022; *Czech Academy of Sciences, 2024*). This response showed that scientific institutions are not morally neutral service providers. They belong to a democratic public sphere and must respond when academic freedom, human life, and research infrastructure are attacked. Supporting researchers at risk is therefore part of research integrity in a broad sense. It defends the conditions under which honest and free research can exist. The Academy's public stance also strengthened its identity as a European institution committed to democratic values.

Public accountability also requires communication with society. The Academy's Strategy AV21, adopted under the motto "Top research in the public interest", represents a deliberate attempt to connect high-level research with contemporary social challenges (*Czech Academy of Sciences, 2014*; *Strategy AV21, n.d.*). This strategy matters because it prevents accountability from being understood only as financial reporting or legal compliance. The Academy must also show that its expertise contributes to health, education, energy, environment, technology, culture, public policy, and social resilience. Strategy AV21 gives institutional form to this claim by organising interdisciplinary programmes around problems relevant to society. It therefore connects research excellence with public responsibility.

Science communication is another major component of accountability. The Academy's development documents emphasise popularisation, public events, media communication, internet and social media, Science Fair, Week of the Czech Academy of Sciences, and popular science magazines as means of bringing research closer to society (*Czech Academy of Sciences, 2025*). Such activities are not decorative. In a society vulnerable to misinformation, distrust, and politicisation of expertise, science communication is part of the public mission of research institutions. It helps citizens understand why research matters, how knowledge is produced, and what uncertainty means. It can also attract young people to science. The Academy's public communication therefore supports both democratic culture and future scientific capacity.

However, public communication must itself observe integrity. Popularisation can become misleading if it exaggerates certainty, overpromises applications, hides limitations, or simplifies controversies irresponsibly. The Academy must therefore communicate in a way that is clear but not manipulative. This is particularly important in fields such as health, climate, energy, artificial intelligence, migration, history, and social conflict, where public debates can be polarised. Transparency means acknowledging uncertainty, explaining methods, and distinguishing evidence from speculation. Public accountability does not require scientists to be omniscient. It requires them to be honest about what is known, what is uncertain, and why further research matters.

The COVID-19 pandemic demonstrated the importance and difficulty of this role. Scientific institutions across Europe were expected to provide expertise, communicate uncertainty, respond to misinformation, and maintain public trust under rapidly changing conditions. For the Academy, the pandemic confirmed that public accountability cannot be activated only in moments of crisis; it must be built beforehand through credibility, communication channels, and a culture of transparency. It also showed that science is often most visible to the public when evidence is incomplete and politically contested. This places heavy responsibility on researchers and institutions. Integrity under crisis conditions means resisting both silence and overstatement.

The Academy's public accountability also includes preservation of institutional memory. Archives, annual reports, digital libraries, evaluation documents, codes of ethics, and public statements create a record through which future researchers and citizens can examine the institution's conduct. This is especially important for an academy whose history includes periods of political subordination and ideological distortion. Transparency towards the future is part of accountability in the present. The Masaryk Institute and Archives, the Library of the CAS, digital repositories, and published documents collectively ensure that the Academy's actions are not lost to institutional amnesia. A transparent institution preserves the sources through which it can later be studied critically.

The relationship between transparency and privacy must also be managed carefully. Research organisations handle personal data concerning employees, students, collaborators, participants, reviewers, applicants, and complainants. Ethical procedures, misconduct investigations, ombudsperson cases, and personnel matters often require confidentiality. Public accountability therefore cannot mean total disclosure of every institutional process. The Academy must protect individuals while maintaining trust in procedures. This is a difficult balance. Excessive secrecy can weaken confidence; excessive exposure can harm people and discourage reporting. Mature transparency distinguishes between public principles, procedural clarity, and necessary confidentiality.

The legal environment of public research also shapes accountability. As a public institution, the Academy operates within Czech laws concerning state property, public funding, access to information, employment, data protection, and research support. Its Head Office and institutes must manage resources, reporting, contracts, and governance in accordance with this legal framework. This legal accountability is different from scientific evaluation but connected with it. Research quality cannot compensate for irresponsible financial or administrative conduct, and good administration cannot replace scientific excellence. A modern academy must sustain both. Public trust depends on the integrity of research and the integrity of institutional management.

The Academy's institutes as public research institutions have their own accountability structures. Directors, boards, supervisory mechanisms, annual reports, budgets, and institute regulations create local frameworks of responsibility. This decentralised accountability is important because most research integrity issues arise at the institute or team level. Central codes and committees matter, but daily culture is shaped by laboratories, departments, seminars, archives, field teams, and project groups. Institute leadership therefore has a decisive role in creating environments where ethical behaviour is normal, complaints can be raised safely, and quality is valued over superficial performance. The Academy's integrity depends on the cumulative conduct of its institutes.

The human dimension of accountability becomes especially visible in supervision and mentoring. Doctoral students, postdoctoral researchers, and early-career scientists are vulnerable to power imbalances. They may depend on supervisors for funding, authorship, recommendations, visas, contracts, and career opportunities. A research institution committed to integrity must therefore ensure that supervision is fair, respectful, and professionally responsible. This includes clear expectations, appropriate credit, protection from exploitation, and mechanisms for resolving conflicts. The Academy's broader concern with safe and respectful working environments is therefore directly linked to the future of research quality. Poor mentoring damages both people and science.

Research integrity also requires attention to equality and inclusion. Discrimination, unequal opportunities, and hostile working environments can distort scientific careers and waste talent. The Code of Ethics includes equal opportunities among the basic values of the academic environment (*Czech Academy of Sciences, n.d.*). This principle has practical implications for recruitment, promotion, leadership, evaluation, mobility, parental leave, and access to resources. Public accountability demands that a national research institution not reproduce hidden barriers while speaking in the name of excellence. Excellence itself depends on fair access to conditions in which researchers can develop. Integrity and equality therefore belong together.

The Academy's engagement with responsible research assessment reinforces this point. If evaluation systems reward only a narrow range of outputs or career patterns, they may disadvantage researchers with non-linear careers, care responsibilities, interdisciplinary profiles, public-engagement work, or different disciplinary traditions. The Academy's CoARA Action Plan and its emphasis on diverse contributions and qualitative peer review respond to this problem (*Czech Academy of Sciences, 2024*). Responsible assessment is part of public accountability because it shapes what kind of research culture public money supports. A fair evaluation system is not only technically better; it is ethically more defensible. It helps align institutional incentives with the values the Academy publicly declares.

Public accountability also requires the Academy to defend science against misuse. Research results can be politicised, commercialised irresponsibly, taken out of context, or used to support harmful agendas. This risk is especially visible in areas such as genetics, artificial intelligence, environmental policy, migration, historical memory, and national identity. The Academy cannot control all uses of knowledge, but it can communicate carefully, maintain ethical standards, and intervene when public misrepresentation is serious. Its credibility depends on a willingness to clarify, correct, and explain. Transparency therefore includes responsiveness. A public research institution must not only publish results; it must participate responsibly in the public life of those results.

The relationship between research integrity and trust is therefore reciprocal. Society grants the Academy resources, autonomy, and authority because it trusts that researchers work honestly and responsibly. The Academy earns and renews that trust through ethical conduct, openness, evaluation, communication, and accountability. Trust cannot be demanded as an entitlement. It must be maintained through visible practice. This is one of the fundamental differences between democratic public science and politically protected institutional science. In the democratic model, autonomy survives only when institutions show that they deserve it. Research integrity is thus not a restriction on autonomy. It is one of its conditions.

By the mid-2020s, AV ČR had developed a relatively dense ecosystem of integrity and accountability: a Code of Ethics for researchers, a Code of Conduct, a Scientific Integrity Committee, an ombudsperson, open science principles, evaluation reforms, annual reports, public communication strategies, Strategy AV21, and participation in European integrity and assessment frameworks. This ecosystem is still evolving, and it does not guarantee the absence of problems. No research institution can eliminate misconduct, conflict, inequality, or public misunderstanding entirely. What matters is whether institutions possess principles, procedures, cultures, and willingness to respond. The Academy's modernisation can therefore be measured not only by research achievements but by its capacity to recognise and address ethical and public responsibilities.

The historical importance of this development becomes clearer when placed against the entire trajectory of the Academy. Earlier scientific societies sought legitimacy through learned authority and service to national culture. ČSAV under socialism combined genuine research with ideological subordination and state hierarchy. The post-1989 Academy reconstructed autonomy through reform, evaluation, and internationalisation. The contemporary Academy must now sustain autonomy through transparency, integrity, openness, and public responsibility. Each period had its own form of legitimacy. In the present, legitimacy depends increasingly on the ability to combine excellence with trust. This makes research integrity one of the defining features of the Academy's modern institutional identity.

Thus, research integrity, transparency, and public accountability represent the ethical and civic core of the Czech Academy of Sciences' modernisation. The Academy's Code of Ethics, Scientific Integrity Committee, ombudsperson, open science principles, evaluation reforms, annual reports, Strategy AV21, and public communication activities all contribute to a culture in which autonomy is inseparable from responsibility. This transformation reflects both Czech post-socialist experience and wider European developments in research integrity, responsible assessment, open science, and science-for-policy. It shows that a modern academy of sciences cannot rely on historical prestige or state support alone. It must earn public trust through honest research, fair working environments, transparent procedures, responsible communication, and willingness to submit itself to scrutiny. In this sense, integrity and accountability are not external constraints on the Academy's scientific mission. They are the conditions under which that mission can remain credible, democratic, and socially meaningful.

Career Structures and the Human Dimension of Modernisation

1. Research Careers in the Academy

Research careers in the Czech Academy of Sciences form one of the most revealing dimensions of its modernisation after 1993. Institutional reform, funding competition, European integration, open science, and research evaluation all ultimately affected the people who made the Academy function: researchers, doctoral students, postdoctoral fellows, institute directors, laboratory leaders, archivists, data specialists, and research-support professionals. The transformation of AV ČR was therefore never only a matter of laws, councils, budgets, institutes, or programmes. It was also a transformation of academic lives. A research career that had once been shaped by the relatively closed structures of a state-socialist academy became increasingly dependent on open recruitment, periodic evaluation, grant competition, international mobility, publication visibility, project networks, and institutional support for excellence. The modern Academy did not simply inherit a scientific workforce; it had to create a new career environment in which scientific autonomy, accountability, stability, and competitiveness could coexist.

The early post-transformation years created a difficult starting point for this career system. The restructuring of the Czechoslovak Academy and the birth of the Czech Academy of Sciences

involved major reductions in personnel, the abolition or transformation of institutes, and a sharp change in the relationship between research work and public funding. For many researchers, the 1990s were experienced not only as democratic liberation but also as institutional uncertainty. Some gained opportunities to travel, publish, collaborate, and lead research more freely than before. Others lost positions, saw their institutes reorganised, or had to adapt to standards and forms of competition that were unfamiliar. The career structure of the new Academy therefore emerged from a double experience: the recovery of academic freedom and the loss of the old guarantees of institutional employment. This duality continued to shape research careers for decades (*Filáček, 2023*; *Linková, 2015*).

Under the socialist model, a research career in the Academy had often been embedded in a relatively stable institutional hierarchy. This stability could protect long-term research, but it could also reproduce political dependence, bureaucratic inertia, and limited openness. After 1989, the Academy had to replace this model with a system based on scientific quality, internal evaluation, open selection, and international standards. The question was not simply how to employ scientists, but how to create a career order compatible with democratic research governance. Careers had to be regularised without becoming rigid; evaluated without becoming purely metric-driven; internationalised without producing permanent brain drain; and opened to younger researchers without destroying institutional memory. These tensions made career policy one of the most delicate areas of modernisation.

The legal and organisational form of the Academy shaped this career environment. AV ČR is not a university, although its institutes contribute significantly to doctoral training and many Academy researchers teach at universities. It is a system of public research institutes whose primary mission is research across natural, technical, social sciences, and humanities. This gives Academy careers a distinctive character. Researchers often have less regular teaching responsibility than university academics, but they may face stronger expectations of project work, publication output, laboratory or archival productivity, international cooperation, and participation in institute-level research strategy. The Academy's career model therefore differs from the classical university professorial path. It is closer to a research-institute model in which scientific performance, team development, project leadership, and infrastructure use are central.

The Career Development Rules for CAS employees with a university degree gave this model a formal structure. Approved by the Academy Assembly in 2008, the rules regulate the position of university-educated employees at research departments of CAS institutes and explicitly refer to the European Charter for Researchers and the Code of Conduct for the Recruitment of Researchers (*Czech Academy of Sciences, 2008*). This reference is important because it places Academy careers within a European framework of transparent recruitment, professional development, ethical responsibility, and attractive research environments. The rules were not merely internal personnel regulations. They represented an attempt to define what a research career in the Academy should mean in the post-socialist and Europeanised period. They linked individual advancement with evaluation, qualification, salary, professional growth, teaching, and public outreach.

Recruitment by selection procedure became one of the formal foundations of this system. According to the Career Development Rules, employees are recruited on the basis of a selection procedure announced by the director of a CAS institute (*Czech Academy of Sciences, 2008*). This principle matters because open recruitment is a key difference between a modern

research institution and a closed academic corporation. It does not guarantee perfect fairness by itself, since recruitment procedures depend on advertisement, committee composition, criteria, institutional culture, and the wider labour market. Yet it creates a formal expectation that positions should not be distributed only through informal patronage or inherited internal networks. In a post-socialist context, this expectation carried special significance. It helped move the Academy away from older patterns of appointment shaped by loyalty, hierarchy, or personal dependence.

The qualification structure established by the Career Development Rules is one of the clearest expressions of the Academy's career logic. It includes research assistant, graduate student, postdoctoral fellow, associated scientist or scholar, scientist or scholar, and senior scientist or scholar (*Czech Academy of Sciences, 2008*). This sequence creates a pathway from support roles and doctoral training towards independent research and recognised leadership. The postdoctoral category is defined as temporary and limited to no more than five years after receiving the doctoral degree. The scientist or scholar grade assumes independent work and regular publication in peer-reviewed domestic or foreign journals or magazines, usually with involvement in grant or programme projects. The senior scientist or scholar grade identifies a leading scientific personality significantly involved in the development of the field at international level. Thus, the Academy's career structure combines professional progression with expectations of independence, productivity, international visibility, and scientific leadership.

The postdoctoral stage is particularly important because it is often the most fragile moment in a research career. Postdoctoral researchers are expected to demonstrate independence, publish, obtain project experience, build international networks, and prepare for more stable positions. Yet they often work under fixed-term contracts and depend on grants, supervisors, or institute resources. This is not only a Czech issue. Across OECD countries, postdoctoral careers have become associated with uncertainty, temporary employment, and competition for a limited number of permanent positions (*OECD, 2021*). The Academy's postdoctoral category therefore reflects a broader European problem: research systems need postdocs as engines of scientific productivity and renewal, but they often struggle to offer them predictable career prospects. The human dimension of modernisation is especially visible here, where opportunity and precarity coexist.

The category of associated scientist or scholar also reveals this tension. It applies to employees who have not been assigned to the higher scientist or senior scientist categories within five years of obtaining the doctorate (*Czech Academy of Sciences, 2008*). This grade recognises that not all research careers progress at the same speed or according to the same linear model. Some researchers may need more time because of field conditions, family responsibilities, interdisciplinary work, health, mobility, or the rhythm of long-term projects. At the same time, the category can also mark a career bottleneck. It shows that the Academy's career system must distinguish between temporary developmental stages and stagnation. A modern personnel policy must therefore combine standards with sensitivity to the real biographies of researchers. If evaluation is too rigid, it may damage talent; if it is too loose, it may weaken institutional quality.

Periodic evaluation is central to the Academy's career structure. The Career Development Rules state that the performance, creativity, results, and achievements of employees are regularly evaluated, that evaluation results determine qualification grade placement, and that

qualification grade affects career advancement and salary (*Czech Academy of Sciences, 2008*). Researchers are evaluated at least once every five years. The declared purposes of evaluation include improving scientific activity, creating a basis for sound human resources policy, comparing results within qualification grades, stimulating professional growth, and giving employees an opportunity for self-reflection (*Czech Academy of Sciences, 2008*). This formulation shows that evaluation is meant to be both formative and consequential. It is not only a judgement on past work, but also a mechanism for future development.

At the level of the individual researcher, evaluation creates a direct connection between research performance and career security. This connection can strengthen quality and discourage complacency. It can also generate pressure, especially when evaluation is linked to salary, qualification grade, or the duration of the employment contract. The Career Development Rules allow evaluation committees to propose whether an employment contract should be indefinite or fixed-term and to recommend its duration (*Czech Academy of Sciences, 2008*). Such procedures make research careers more accountable, but they also make them more vulnerable to institutional judgement. The crucial question is therefore whether evaluation is fair, transparent, field-sensitive, and capable of recognising different forms of contribution. A career system based on evaluation must constantly guard against reducing research lives to narrow output measures.

The Academy's individual career evaluation must also be understood in relation to institute evaluation. Researchers work within teams, laboratories, departments, and institutes that themselves undergo periodic assessment. A strong institute evaluation can create opportunities for researchers, attract funding, support new positions, and improve infrastructure. A weak institute evaluation can lead to restructuring, pressure on teams, and uncertainty for staff. Careers are therefore shaped by both individual and institutional assessment. This is one of the characteristic features of a research-institute system. A researcher's trajectory depends not only on personal achievement, but also on the strategic health of the institute, the success of the team, the quality of leadership, and the ability to secure resources. The human dimension of evaluation is therefore more complex than a simple relationship between individual merit and reward.

The Academy's career rules also insist that employees should not be discriminated against during evaluation in terms of gender, age, origin, religion, political opinion, or other similar grounds (*Czech Academy of Sciences, 2008*). This principle is essential because research careers are vulnerable to hidden inequalities. Formal excellence criteria can reproduce unequal conditions if institutions ignore care responsibilities, mobility barriers, unconscious bias, disciplinary differences, or informal networks of recognition. Non-discrimination in evaluation is therefore not a decorative phrase. It is one of the conditions under which scientific quality can be judged fairly. In the Academy's historical context, it also marks a departure from earlier political and ideological forms of exclusion. Democratic career policy requires that researchers be judged by relevant scholarly and professional criteria rather than by identity, loyalty, or personal dependence.

Teaching and public outreach occupy a special place in Academy careers. The Career Development Rules state that employees, depending on their capacities, should contribute to educational and public outreach activities, and that CAS considers teaching to be an important activity performed by employees of its research institutes (*Czech Academy of Sciences, 2008*). This is significant because the Academy is not a teaching university, yet it cannot exist outside

the educational system. Its researchers supervise doctoral students, teach at universities, participate in degree programmes, organise internships, and communicate with schools and the public. This activity strengthens the Academy's role in forming future researchers. It also connects research careers with public responsibility. A researcher in AV ČR is not only a producer of specialised knowledge; he or she is also part of a broader educational and cultural ecosystem.

The collaboration with universities is therefore a central part of career formation. Academy institutes participate in doctoral programmes through cooperation with universities, and many CAS researchers supervise doctoral students or teach in bachelor's and master's programmes. The Academy's strategic documents emphasise that CAS institutes often possess unique facilities and research infrastructures that support university collaboration, and that cooperation with universities is natural for both research and the education of future researchers (*Czech Academy of Sciences, 2025*). For research careers, this means that the Academy offers a distinctive training environment: doctoral students and early-career researchers can work in highly specialised institutes while remaining connected to university degree structures. This hybrid model is one of the strengths of the Czech research system. It allows the Academy to contribute to human capital without becoming a university in the formal sense.

The Doctor of Sciences degree, now associated with the English-language equivalent "Research Professor" or "Res. Prof.", represents another element of career recognition. The Academy's strategic documents describe the degree as expressing a particularly high scientific qualification, proven by significant, original work important for the development of a research field and characterising a leading figure (*Czech Academy of Sciences, 2025*). The degree is not limited to Academy employees, but within AV ČR it also serves as one of the criteria for achieving the highest qualification degree according to the career rules. Its existence reflects a Central European tradition of advanced scholarly recognition beyond the PhD. In the modern Academy, it functions as both symbolic distinction and career marker. It connects contemporary research careers with older forms of learned authority, but under conditions of peer evaluation and scientific achievement rather than inherited status.

Recognition and support programmes became increasingly important instruments of career development. The Otto Wichterle Award, intended for exceptionally promising young scientists at CAS who have already obtained a scientific degree and are generally under 35, encourages early excellence and gives public visibility to young researchers (*Czech Academy of Sciences, n.d.*). The Programme to Support Prospective Human Resources – Postdoctoral Fellows supports beginning postdoctoral researchers and helps them establish themselves in CAS institutes (*Czech Academy of Sciences, 2023*). Lumina Quaeruntur supports mid-career researchers, including those returning after parental leave, in establishing their own research groups, with substantial support over several years (*Czech Academy of Sciences, 2024*). Praemium Academiae provides major long-term support for outstanding senior researchers (*Czech Academy of Sciences, n.d.*). Together, these instruments create a layered ecosystem of career support from postdoc to scientific leader.

The J. E. Purkyně Fellowship was especially important for attracting outstanding researchers from abroad. It was designed to bring creative scientists to CAS institutes, including Czech scientists working abroad for long periods and top foreign researchers, usually younger than 45, with adequate financial conditions for up to five years (*Czech Academy of Sciences, n.d.*).

This fellowship addressed a central problem of post-socialist research systems: how to turn international openness into brain circulation rather than one-way brain drain. If talented Czech researchers left for better-equipped institutions abroad, the Academy needed mechanisms to bring some of them back or maintain their connection with Czech science. If foreign researchers could be attracted to CAS institutes, they could bring new methods, networks, mentoring practices, and project ambitions. The fellowship therefore linked career policy with internationalisation and institutional renewal.

The Academy's career support system increasingly had to respond to the changing European research environment. The European Charter for Researchers and the Human Resources Strategy for Researchers emphasise attractive and sustainable research careers, ethical and transparent recruitment, working conditions, mobility, assessment, career development, and talent retention (*European Commission, 2023*; *EURAXESS, n.d.*). These themes became increasingly relevant for AV ČR because the Academy competes not only within the Czech labour market, but within a European and global market for research talent. Salaries, infrastructure, mentoring, international project opportunities, family support, and career transparency all affect whether researchers choose to remain in or come to Czech institutes. Career policy therefore became part of international competitiveness. It was no longer a purely internal personnel matter.

Project-based funding deeply affected research careers. Grants from GA ČR, TA ČR, EU Framework Programmes, ERC, MSCA, and other sources created opportunities for researchers to build teams, obtain equipment, travel, publish, and gain independence. At the same time, project-based funding increased dependence on temporary contracts, short cycles, proposal success, and administrative work. This is one of the structural contradictions of modern research careers. Competition stimulates initiative and excellence, but it can also produce insecurity and fragmentation. Researchers may spend significant time preparing applications, managing budgets, reporting outputs, and ensuring continuity between grants. The Academy's career system had to operate within this project economy while preserving the long-term conditions needed for serious research.

This tension is particularly visible in early and mid-career stages. A young researcher may move from doctoral student to postdoctoral fellow, then to associated scientist or project-funded researcher, while seeking a path towards independent scientist status. Success depends on publications, grants, mobility, mentors, institute priorities, available positions, and sometimes luck. Mid-career researchers face another bottleneck: they are expected to lead projects and teams, but may not yet have the security, resources, or recognition of senior figures. Lumina Quaeruntur and related programmes respond to precisely this stage by helping promising researchers create their own groups. Such instruments are important because career systems cannot rely only on spontaneous emergence of leaders. They must actively create pathways for independence.

International mobility became a normal expectation in Academy careers. Researchers increasingly needed foreign stays, international co-authorship, European projects, conference visibility, and participation in transnational networks. Mobility brought major benefits: new methods, tacit knowledge, language competence, professional confidence, and access to global standards. Yet it also created pressures. Not all researchers can move easily; family responsibilities, health, finances, nationality, visa rules, and care obligations shape mobility opportunities. European policy recognises the value of different forms of mobility, including

transnational, intersectoral, interdisciplinary, and virtual mobility (*European Commission, 2023*). For the Academy, the challenge was to support mobility without treating it as a rigid marker of merit. A good career system recognises mobility as valuable but not identical with excellence.

Research careers in the Academy are also shaped by the relationship between autonomy and teamwork. In many disciplines, especially laboratory sciences, individual achievement is inseparable from team organisation, infrastructure, technical staff, shared equipment, and collective publication. In humanities and some social sciences, individual monographs and interpretations remain important, but even there research increasingly depends on databases, archives, projects, and networks. The Academy's career system must therefore evaluate both individual contribution and collective context. A researcher may be a brilliant independent scholar, an essential team scientist, a method specialist, a project coordinator, or an infrastructure builder. Modern career evaluation must recognise this variety. Otherwise, it risks rewarding only the most visible forms of authorship and leadership.

Technical and professional staff are often underrepresented in narratives of research careers, but they are indispensable to the Academy's functioning. Laboratories require technicians, data specialists, animal-care staff, instrument engineers, software developers, collection managers, archivists, librarians, project managers, and administrators. Some hold university degrees and fall within professional or development categories; others support research in less visible roles. The Academy's modernisation increased their importance because research became more technologically complex, administratively demanding, and data-intensive. A successful institute is not only a group of principal investigators. It is a working environment in which many kinds of expertise support knowledge production. The human dimension of the Academy therefore extends beyond the narrow figure of the senior scientist.

The emergence of research administration as a professional field changed career structures indirectly. European projects, open science, data management, intellectual property, evaluation, ethics, and public communication all require specialised support. Project managers, grant officers, legal advisers, communication specialists, and data stewards became increasingly important to scientific success. Their careers may not follow the same qualification grades as researchers, but their work shapes the possibilities available to researchers. This development reflects a broader transformation of research institutions into complex organisations. Scientific excellence now depends on administrative and infrastructural competence. The Academy's career culture must therefore value both researchers and those who make research possible.

Salary competitiveness remained a persistent issue. The Academy had to attract and retain talented researchers in a labour market where salaries in Western Europe, North America, and sometimes private industry could be much higher. Public research funding in the Czech Republic has often been below the level needed to eliminate these disparities fully. Career advancement through qualification grades and internal payroll rules can provide structure, but it cannot solve the broader funding problem alone. This is why institutional stability, grant opportunities, fellowships, good infrastructure, intellectual autonomy, and meaningful research environments are so important. Researchers may accept lower salaries if they have strong scientific conditions, but there are limits. Career modernisation therefore depends on national investment as well as internal rules.

The Academy's strategic documents recognise human resources as a core condition of institutional future. They emphasise the need to ensure an appropriate quality and age structure among researchers, maintain perspective for research teams, obtain talented students and early-career researchers, and attract high-quality researchers from abroad (*Czech Academy of Sciences, 2025*). This language shows that career policy is not simply an administrative function. It is a strategic question of institutional survival. A research institute can possess excellent infrastructure, but without talented people it cannot remain alive. It can have famous senior figures, but without generational renewal it becomes fragile. It can attract young researchers, but without career prospects it may lose them. The Academy's future therefore depends on managing careers across the entire life cycle.

The "Academy of the Future" initiative expresses this life-cycle perspective in a more programmatic form. Its aim is to create conditions for career development of CAS employees, support integration into the international scientific community, provide working conditions enabling optimal use of human and intellectual potential, and help combine research activity with personal life (*Czech Academy of Sciences, n.d.*). Its planned instruments include fellowships for researchers at the beginning of an independent scientific career, fellowships for researchers, improved conditions for obtaining and managing major projects, return after career breaks, recruitment of talented researchers from abroad, and support for excellent research groups. This is a significant evolution from older personnel policy. It recognises that research careers are not simply ladders of qualification, but complex biographies shaped by mobility, family, project work, leadership, breaks, return, and institutional culture.

The ability to combine research with personal life is particularly important. For a long time, academic careers were often imagined around a model of uninterrupted mobility, long working hours, and continuous productivity. This model disadvantages researchers with care responsibilities, health issues, or non-linear life trajectories. A modern Academy cannot afford to lose talent because career structures are too rigid. Support for return after career breaks, recognition of parental leave in age limits for awards, and gender equality plans all reflect a more realistic understanding of research lives. Career modernisation therefore requires institutions to see researchers not only as output producers but as people with biographies. The human dimension of modernisation becomes literal here.

Research careers in the Academy also involve public responsibility. Researchers are expected not only to publish and obtain grants, but also to contribute to outreach, education, expert advice, and the dissemination of knowledge. This expectation is rooted in the Academy's public mission and strengthened by Strategy AV21 and open science. It broadens the meaning of a successful career. A researcher may contribute through policy advice, public lectures, media communication, citizen science, educational materials, or service on expert bodies. These activities take time and should be recognised in career evaluation. If they are praised rhetorically but ignored in promotion and salary decisions, researchers will receive contradictory signals. Responsible career structures must align declared public mission with actual incentives.

Research integrity and workplace culture also belong to the career system. A scientist's career develops within relationships of supervision, collaboration, authorship, peer review, leadership, and institutional power. The Academy's Code of Ethics, Code of Conduct, Scientific Integrity Committee, and ombudsperson mechanisms help define the standards under which these relationships should operate (*Czech Academy of Sciences, 2024*; *Czech*

Academy of Sciences, 2025). A career system cannot be healthy if it tolerates harassment, bullying, discrimination, authorship abuse, or retaliation. Young researchers are especially vulnerable to such problems because their future depends on supervisors, team leaders, and directors. Ethical infrastructure therefore supports not only moral standards but also career development. Safe and respectful working environments are a condition of scientific excellence.

The relationship between career and evaluation remained one of the central tensions of modernisation. Evaluation can support growth, identify excellence, and create fairer advancement. It can also produce anxiety, excessive reporting, or pressure to prioritise countable outputs over meaningful research. The Academy's movement towards responsible research assessment is therefore highly relevant to careers. If institute evaluation and individual career evaluation recognise diverse contributions, qualitative peer review, open science, mentoring, public engagement, and interdisciplinary work, career paths can become broader and healthier. If evaluation remains dominated by narrow metrics, researchers will adapt to those metrics. Career culture is therefore one of the places where research assessment reform becomes real.

By the mid-2020s, research careers in AV ČR had become more structured, more competitive, more international, and more reflexive than in the early post-transformation period. The Academy had qualification grades, periodic evaluation, recruitment procedures, support programmes for postdocs, young scientists, mid-career group leaders, senior excellence, returnees, and foreign researchers. It also had growing attention to open science, integrity, international mobility, public outreach, and work-life balance. These developments marked a significant institutional achievement. Yet they also revealed continuing vulnerabilities: fixed-term contracts, funding uncertainty, salary competition, uneven mentoring, administrative burden, mobility pressures, and the risk of losing talented researchers to better-resourced systems. The modern career system was therefore not a finished solution, but an evolving compromise between stability and competition.

The career structure of the Academy should finally be seen as part of the broader history of scientific autonomy. In the early post-1989 period, autonomy meant freedom from ideological control. In the modern Academy, autonomy also means the capacity of researchers to build meaningful careers under fair, transparent, and supportive conditions. A scientist cannot be truly autonomous if he or she is trapped in permanent precarity, dependent on arbitrary supervisors, excluded from mobility, or judged by inappropriate metrics. Conversely, autonomy cannot mean exemption from evaluation, public responsibility, or professional standards. AV ČR's career system therefore embodies the same historical tension that runs through the whole chapter: freedom must be joined with accountability, and excellence must be joined with institutional care.

Thus, research careers in the Czech Academy of Sciences reveal the human substance of institutional modernisation. Since 1993, the Academy has moved from the disrupted career world of post-socialist restructuring towards a structured but demanding system based on selection procedures, qualification grades, periodic evaluation, international mobility, project competition, and support for scientific excellence. Its career instruments — from postdoctoral support and the Otto Wichterle Award to Lumina Quaeruntur, Praemium Academiae, the J. E. Purkyně Fellowship, the Research Professor degree, and newer career-development initiatives — show an effort to build pathways across different stages of scientific life. At the same time,

the Academy's career system remains marked by tensions between stability and flexibility, competition and support, autonomy and evaluation, international mobility and personal life, individual excellence and team science. These tensions are not accidental defects. They are the living form of a modern public research institution trying to sustain scientific quality while caring for the people who produce it.

2. Generational Renewal and Early-Career Researchers

Generational renewal became one of the most important human questions in the modern history of the Czech Academy of Sciences. After 1993, the Academy did not merely have to preserve institutes, budgets, international links, and research infrastructures. It also had to ensure that scientific communities would not age into institutional memory without renewal. A research institute can survive administratively for many years, but without new researchers it gradually loses methodological freshness, intellectual risk, technological competence, and contact with changing international standards. The issue of early-career researchers therefore belongs at the centre of the Academy's modernisation. It connects doctoral training, postdoctoral careers, international mobility, evaluation, mentorship, gender equality, funding, leadership succession, and the long-term reproduction of scientific excellence. Generational renewal is the point where institutional history becomes biography.

The post-socialist transformation created a difficult demographic and professional inheritance. The Academy emerged from the restructuring of ČSAV after large personnel reductions, abolished or reorganised institutes, and a sharp change in the meaning of scientific employment. Many senior researchers remained indispensable because they preserved knowledge, schools, archives, instruments, and international contacts. Yet the Academy could not be renewed only through the authority of older generations. It had to attract young researchers educated in a very different political and scientific environment. These younger researchers entered science after the opening of borders, the rise of grant competition, access to European programmes, digital communication, and new standards of evaluation. Their careers were shaped less by the old institutional ladder and more by doctoral mobility, postdoctoral experience, publications, projects, and international networks. The Academy's generational renewal therefore meant the coexistence of historical continuity and a new research habitus (*Filáček, 2023*; *Linková, 2015*).

The first level of generational renewal was doctoral training. Although the Academy is not a university, its institutes play a major role in the formation of doctoral researchers through cooperation with universities, joint supervision, laboratory training, field research, archival work, and participation in research projects. The Academy's development concept explicitly describes education and the preparation of new researchers as a significant part of its mission, stressing that the expert capacities concentrated in CAS institutes should be used to train researchers for the needs of the Academy, universities, and employment outside academia (*Czech Academy of Sciences, 2025*). This is a crucial statement because it defines the Academy not only as a workplace for already formed scientists but also as a training environment. Its laboratories, libraries, archives, observatories, and research teams become spaces where the next generation learns scientific practice. In this sense, doctoral training is one of the hidden foundations of institutional continuity.

The Academy's contribution to doctoral education also reshaped its relationship with universities. The old separation between Academy institutes as research centres and universities as teaching institutions became increasingly inadequate. Modern doctoral education requires access to active research environments, specialised equipment, international teams, and long-term projects. CAS institutes often provide precisely these conditions, while universities provide degree structures, teaching frameworks, and formal academic accreditation. The Academy's strategic documents therefore emphasise the development of cooperation with universities, including joint research projects, joint workplaces, supervision of dissertations, participation in teaching, and the possible development of joint doctoral schools (*Czech Academy of Sciences, 2025*). Generational renewal thus becomes a bridge between institutional sectors. It allows the Academy and universities to share responsibility for forming future researchers rather than competing for symbolic primacy.

Doctoral students in CAS institutes encounter research as practice rather than only as curriculum. They learn how to work with instruments, datasets, archives, field sites, software, manuscripts, specimens, models, sources, and project teams. They also learn the social norms of science: seminar discussion, authorship, peer review, grant preparation, conference presentation, and cooperation across disciplines and borders. This experiential learning is one of the Academy's strengths. A doctoral student embedded in a strong institute can see how research is actually produced, not only how it is described in lectures. Yet this model also creates responsibility. Institutes must provide proper supervision, integration, career guidance, and protection from dependence on individual supervisors. A doctoral student is not only inexpensive labour or a temporary project assistant. He or she is part of the future human capital of Czech science.

The transition from doctoral study to postdoctoral work is often the most difficult passage in a scientific career. It is the stage at which researchers are expected to demonstrate independence, build an international profile, publish significant results, secure grants, and prepare for a more stable position. At the same time, postdoctoral positions are frequently temporary, project-funded, and dependent on the strategies of senior researchers or institutes. The Academy recognised this vulnerability through the Programme to Support Prospective Human Resources – Postdoctoral Fellows, which was designed for beginning postdoctoral researchers at CAS institutes (*Czech Academy of Sciences, 2023*). Such support matters because the immediate postdoctoral period can determine whether a young researcher remains in science or leaves for other sectors. It is a moment of high potential and high risk. Generational renewal therefore depends heavily on how the Academy manages this stage.

Postdoctoral support is not only a financial instrument. It is an institutional statement that the Academy understands early independence as something that must be cultivated. A postdoctoral fellow needs salary support, but also mentorship, research space, access to equipment, integration into a team, training in grant applications, and opportunities for international mobility. Without these conditions, a postdoctoral position may become a temporary holding pattern rather than a real career stage. The Academy's career rules define the postdoctoral fellow as a temporary category normally limited to the period shortly after receiving the doctoral degree (*Czech Academy of Sciences, 2008*). This definition can encourage timely progression, but it also places pressure on researchers to produce visible

results quickly. The quality of postdoctoral policy therefore lies in the balance between demanding standards and meaningful support.

The Otto Wichterle Award is one of the Academy's most visible instruments for recognising promising young scientists. It is awarded to selected, exceptionally outstanding young researchers at CAS who have made remarkable contributions to scientific knowledge, with eligibility normally limited to candidates not older than 35 in the calendar year of nomination (*Czech Academy of Sciences, n.d.*). The award has symbolic significance beyond the individual laureate. It communicates that early-career excellence deserves public recognition within the Academy's hierarchy of prestige. It also creates role models across disciplines, including natural sciences, technical sciences, humanities, and social sciences. The name of Otto Wichterle itself connects young scientific promise with the moral memory of post-1989 academic renewal. The award therefore performs both career-support and institutional-memory functions.

Recognition, however, is not the same as structural renewal. Awards can encourage talented researchers and make them visible, but they cannot by themselves create stable career pathways. Young scientists also need positions, mentoring, predictable evaluation, fair competition, family-compatible working conditions, and opportunities to lead projects. This is why the Academy's human-resource strategy has gradually moved from isolated prizes towards a more comprehensive support ecosystem. Its development concept lists several instruments for human resources and excellence, including postdoctoral support, the Otto Wichterle Award, the Prize of the Czech Academy of Sciences for Young Researchers, Lumina Quaeruntur, Praemium Academiae, the Research Professor degree, career rules, institute evaluation, and international advisory boards (*Czech Academy of Sciences, 2025*). Such a system recognises that generational renewal is not achieved by one measure. It requires a ladder of opportunities across several career stages.

Lumina Quaeruntur occupies a particularly important position in this ladder. It is intended for mid-career researchers, including those returning after parental leave, and is designed to help laureates establish their own research groups with substantial support over several years (*Czech Academy of Sciences, 2025*). This is crucial because generational renewal is not completed when a researcher receives a postdoctoral fellowship or a young-scientist award. The next challenge is the transition from promising individual to independent group leader. Many research systems lose talented people at this stage because they lack resources to build teams, obtain equipment, hire students or postdocs, and develop a distinctive programme. Lumina Quaeruntur addresses this bottleneck by supporting researchers who are ready to define new scientific directions. It therefore transforms generational renewal from recognition of promise into institutional empowerment.

The possibility of return after parental leave is particularly significant. Academic careers have often been structured around an unrealistic model of uninterrupted productivity, continuous mobility, and linear advancement. This model disadvantages researchers with care responsibilities and especially affects women, though not only women. By explicitly including researchers returning from parental leave within a major excellence instrument, the Academy acknowledged that career breaks need not indicate lower scientific potential (*Czech Academy of Sciences, 2025*). This is a small but important cultural shift. It suggests that modern excellence policy must account for real human lives. Generational renewal cannot depend

only on those who fit the old uninterrupted career pattern. It must create conditions for talented researchers to return, rebuild momentum, and lead.

The Academy of the Future programme broadened this life-cycle logic still further. It was designed to create conditions for career development of CAS employees, support their integration into the international scientific community, provide working conditions that allow optimal use of human and intellectual potential, and help them combine research activity with personal life (*Czech Academy of Sciences, n.d.*). Its support types include fellowships for researchers at the beginning of an independent scientific career, fellowships for researchers, improved conditions for obtaining and managing major projects, return after career breaks, acquisition of talented researchers from abroad, activities of excellent research groups, and pathways from idea to innovation or commercial use (*Czech Academy of Sciences, n.d.*). This is a highly revealing programme because it treats generational renewal as a system rather than a moment. It recognises that young researchers need not only inspiration, but institutional architecture.

The emphasis on beginning independent careers is especially important. In many scientific systems, researchers spend long periods in subordinate positions before receiving real autonomy. They may publish under senior leaders, work on other people's projects, and depend on established laboratories for resources. This can be productive when mentorship is strong, but damaging when hierarchy blocks independence. Fellowships for researchers at the beginning of an independent career help create an earlier space for autonomy. They allow talented researchers to formulate their own questions, recruit collaborators, and become visible as leaders rather than only as team members. For the Academy, this is essential because leadership renewal cannot be postponed indefinitely. Institutes must identify and support emerging scientific personalities before they leave or stagnate.

International mobility is another central element of generational renewal. Early-career researchers trained after 1989 increasingly experienced mobility as an expected part of academic life. Foreign stays, conference participation, Marie Skłodowska-Curie Actions, ERC ambitions, bilateral mobility projects, and international postdoctoral positions became markers of professional development. Mobility can be intellectually transformative because it exposes researchers to new methods, different laboratory cultures, alternative theoretical traditions, and broader networks. It also creates confidence and visibility. Yet mobility is not equally accessible to all. Family responsibilities, financial limits, health, nationality, visas, discipline, language, and institutional support all affect who can move and for how long. A fair system of generational renewal must therefore support mobility while recognising its unequal social conditions.

The J. E. Purkyně Fellowship and similar instruments link mobility with attraction of talent from abroad. The fellowship was designed to bring outstanding creative scientists, including Czech researchers who had worked abroad for long periods and foreign researchers, to CAS institutes for up to five years (*Czech Academy of Sciences, n.d.*). This kind of instrument matters because generational renewal is not only internal replacement. It also involves circulation of people, methods, and intellectual cultures across borders. Researchers returning from abroad can bring new expectations of mentoring, publication, project leadership, and laboratory organisation. Foreign researchers can make institutes more cosmopolitan and internationally connected. The Academy's renewal therefore depends partly on its ability to become attractive

beyond the Czech labour market. This is especially important in a competitive European Research Area.

Brain drain is the shadow side of mobility. After 1989, talented Czech researchers could leave for universities and institutes with better salaries, equipment, and career prospects. Some departures were temporary and productive; others became permanent losses. For early-career researchers, the decision to stay, leave, or return depends on many factors: intellectual freedom, salary, contract stability, access to grants, family life, international networks, and confidence in the future of the institute. The Academy cannot prevent mobility, nor should it wish to do so. Democratic science depends on freedom of movement. The real question is whether mobility becomes circulation or extraction. Programmes that support return, recruitment from abroad, and independent group leadership are therefore essential. They help transform the openness of borders into institutional renewal rather than one-way loss.

Generational renewal also requires attention to the internal age structure of teams. The Academy's development concept explicitly names appropriate quality and age structure among researchers as one of its tasks (*Czech Academy of Sciences, 2025*). This phrase may sound administrative, but it contains a major institutional problem. A team dominated by senior figures may have strong memory but weak renewal. A team made only of short-term young researchers may have energy but little continuity. A healthy research environment needs a mix of doctoral students, postdocs, independent researchers, technical specialists, senior scientists, and mentors. It also needs transparent succession. Leadership cannot be renewed only when a director or principal investigator retires. It must be prepared over time through responsibility, mentoring, and opportunities for younger researchers to lead.

Mentorship is therefore one of the quiet foundations of generational renewal. Formal rules can create positions and evaluations, but the everyday formation of young researchers depends heavily on mentors. A good mentor teaches methods, opens networks, explains unwritten norms, shares credit, protects early-career researchers from exploitation, and gradually gives them independence. A poor mentor can damage careers through neglect, excessive control, authorship abuse, or unclear expectations. The Academy's code of ethics and its newer attention to safe working environments are therefore relevant to early-career policy (*Czech Academy of Sciences, 2024*). Mentorship is not only kindness; it is an institutional mechanism for reproducing scientific quality. The future of an institute often depends on how its senior researchers treat its youngest members.

The evaluation of institutes increasingly reflects this issue. Contemporary CAS evaluation does not consider only outputs and bibliometrics; it also looks at leadership, communication, strategy, infrastructure use, and how institutes work with early-career researchers (*Czech Academy of Sciences, 2026*). This is a significant development. It means that the treatment of young researchers becomes part of institutional quality. An institute cannot claim excellence if it produces papers while failing to train, support, or retain the next generation. Evaluation therefore shifts attention from individual achievement to research environment. It asks whether institutes are places where early-career researchers can develop into independent scientists. This is one of the most important ways in which the human dimension enters research assessment.

Early-career researchers are also affected by the project economy. Grants create opportunities for employment, mobility, equipment, and independent work, but they also produce temporary contracts and uncertainty. A young researcher may move from one project to another without

a clear long-term path. This form of precarity is widespread internationally and has been discussed by the OECD as a serious problem in academic research careers (*OECD, 2021*). The Academy is not isolated from this structural trend. Its institutes depend partly on competitive funding, and early-career researchers often carry a large share of project work. The challenge is to prevent project-based opportunity from becoming permanent insecurity. A modern Academy must use projects to launch careers, not merely to consume early-career labour.

Grant agencies can either worsen or alleviate this problem. The Czech Science Foundation's schemes, including support for early-career researchers, provide opportunities for young scientists to establish independent projects and gain recognition. European instruments such as ERC Starting Grants and MSCA Postdoctoral Fellowships play a similar role at international level. Yet success rates are competitive, and proposal preparation requires mentorship and institutional support. The Academy's ERC Incubator and related support structures respond to this reality by helping researchers prepare stronger proposals and improve competitiveness. For early-career researchers, such support is crucial. It converts institutional knowledge into individual opportunity. It also makes European excellence instruments more accessible to researchers working in Czech institutes.

The relationship between early-career researchers and open science is another new dimension of generational renewal. Younger scholars often enter science in an environment where data management plans, repositories, open access, FAIR principles, research integrity, and transparent methods are increasingly expected. This can give them new skills and make their work more visible, but it can also add administrative burdens at an early stage. Training in open science should therefore be part of career development rather than an additional demand imposed without support. The Academy's Open Science Principles and the Library's support services create an institutional framework for this learning (*Czech Academy of Sciences, 2024*). Early-career researchers are often the generation through which new standards of research culture become normalised. Their education in open science therefore has long-term institutional consequences.

Digitalisation similarly changes the skills expected of young researchers. Data analysis, programming, digital archives, text mining, modelling, visualisation, repository use, and online collaboration are increasingly important across fields. This does not mean that every researcher must become a computer scientist, but it does mean that digital literacy has become part of scientific competence. Young researchers often bring these skills into institutes, thereby contributing to methodological renewal. In humanities and social sciences, digital methods can open new forms of corpus analysis, mapping, network analysis, and archival access. In natural and technical sciences, computational tools are often inseparable from research itself. Generational renewal is therefore also technological renewal. New cohorts change not only who works in the Academy, but how research is done.

The Academy's public-outreach activities also involve young researchers. Open Days, Science Fair, Week of the Czech Academy of Sciences, internships for students, public lectures, media appearances, and educational programmes all help make science visible to younger publics. These activities are important for recruitment because interest in a research career often begins before university. The Academy's development concept explicitly mentions reaching out to secondary school students and primary school pupils, including through internships in the Open Science programme and student competitions (*Czech Academy of Sciences, 2025*). This means that generational renewal begins before doctoral study. It starts with the social

imagination of science. If young people do not see research as meaningful, accessible, and socially valued, the future talent pool narrows.

The Open Science programme for students is therefore part of a broader recruitment ecosystem. It gives talented students opportunities to encounter real research environments, meet scientists, and experience scientific work before making long-term educational choices. Such programmes can be particularly important in a society where science may appear distant or overly specialised. They can also help diversify the future research community by reaching students from different regions, schools, and social backgrounds. Early exposure does not guarantee a scientific career, but it creates possibility. The Academy's role in public education is therefore linked to its future personnel base. Outreach is not only communication; it is long-term recruitment.

Generational renewal also depends on the attractiveness of the Academy as an employer. Young researchers compare possible careers across universities, research institutes, private companies, foreign institutions, and non-academic sectors. They consider salary, stability, intellectual freedom, mentoring, infrastructure, international mobility, family life, and the prestige of the institution. The Academy's programmes can support excellence, but the everyday attractiveness of institutes depends on working conditions. This includes transparent contracts, fair leadership, administrative support, access to grants, reasonable expectations, and respectful culture. An institute that is scientifically strong but socially toxic may lose young talent. The human dimension of modernisation is therefore also a question of organisational climate.

The issue of work-life balance became increasingly visible in the 2020s. The Academy of the Future explicitly aimed to provide conditions that allow researchers to use their human and intellectual potential while combining research with personal life (*Czech Academy of Sciences, n.d.*). This language marks a change in institutional culture. Earlier academic systems often treated personal life as irrelevant to scientific merit. Modern career policy increasingly recognises that sustainable excellence requires attention to care, health, mental well-being, mobility constraints, and career breaks. Early-career researchers are especially affected because they often make major life decisions at the same time as they face the most intense career pressure. Generational renewal will fail if young researchers must choose between serious science and a viable life.

The Academy's support for researchers returning from career breaks therefore has institutional significance. Career breaks can result from parental leave, illness, care responsibilities, or other life events. If the system treats such breaks as career failure, it wastes talent and reproduces inequality. If it provides structured return support, it can preserve expertise and strengthen loyalty to the institution. This is particularly relevant for women researchers, but it is not only a women's issue. A humane and modern research institution recognises that careers are not always linear. The Academy's newer support mechanisms show movement towards this recognition. They also connect generational renewal with the themes of gender and institutional culture that will be discussed in the following section.

International crisis added another dimension to early-career support. After the Russian invasion of Ukraine, the Academy developed support for researchers at risk and for foreign researchers whose work was endangered by war or persecution (*Czech Academy of Sciences, 2025*). Some of these researchers were early-career scientists whose careers could have been destroyed by displacement. Hosting them was not only humanitarian assistance; it also

brought new people, skills, and perspectives into CAS institutes. It reminded the Academy that generational renewal can be shaped by geopolitical events. Research careers do not develop in a vacuum. War, authoritarianism, migration, and threats to academic freedom can abruptly change the lives of young researchers. A modern Academy must be capable of solidarity as well as competition.

The role of young researchers in interdisciplinary programmes is another important aspect of renewal. Strategy AV21 and European projects often require collaboration across disciplines and institutes. Early-career researchers may be more willing than senior scholars to cross disciplinary boundaries, learn new methods, and work in hybrid teams. They are therefore valuable carriers of interdisciplinarity. At the same time, interdisciplinary careers can be risky because evaluation systems and job markets are often still organised around traditional disciplines. The Academy's responsible assessment reforms are therefore important for young researchers working between fields. If their contributions are not recognised properly, interdisciplinarity becomes a rhetorical goal rather than a viable career path.

Generational renewal also affects leadership. The Academy needs future institute directors, department heads, principal investigators, advisory-board members, project coordinators, and public experts. Leadership cannot be improvised when senior figures retire. It must be developed through gradual responsibility, mentoring, management training, and opportunities to lead teams and projects. Programmes supporting independent groups, ERC applications, and international project coordination all contribute to this leadership pipeline. A young scientist who learns only how to publish may not automatically know how to lead people, manage budgets, support students, or communicate with society. Modern career development must therefore include leadership skills as part of scientific maturity. The Academy's future governance depends on this preparation.

The generational problem is also cultural. Younger researchers often bring different expectations concerning openness, hierarchy, work-life balance, gender equality, digital tools, international collaboration, and public communication. These expectations can create tension with older academic habits. Such tension is not necessarily destructive. It can help institutes change. Yet it must be managed constructively. Senior researchers provide memory, caution, and disciplinary depth; younger researchers bring new methods, networks, and expectations. A healthy institute allows these elements to interact rather than turning generational difference into conflict. The Academy's modernisation depends on intergenerational dialogue. Renewal without continuity becomes superficial, while continuity without renewal becomes decline.

The broader European context reinforces the urgency of this issue. European research policy increasingly focuses on attracting and retaining research talent, improving research careers, reducing precarity, supporting mobility, and recognising diverse contributions (*European Commission, 2023*; *OECD, 2021*). AV ČR participates in this context not as an isolated national academy but as part of the European Research Area. Its ability to recruit and retain early-career researchers depends on how it compares with European institutions. If Czech research careers appear less stable, less well paid, or less internationally connected, the Academy risks losing talent. If it offers autonomy, strong teams, excellent infrastructure, and meaningful support, it can become attractive despite resource limitations. Generational renewal is therefore also a question of European competitiveness.

By the mid-2020s, AV ČR had developed a multi-layered system for supporting generational renewal. It included doctoral collaboration with universities, student outreach, postdoctoral

support, early-career awards, mid-career fellowships, return mechanisms, recruitment from abroad, ERC-oriented support, research evaluation attentive to early-career environments, and strategic documents identifying age structure as a core concern. This system did not remove all problems. Fixed-term contracts, grant dependence, salary competition, uneven mentoring, family-care pressures, and disciplinary inequalities remained. Yet the existence of such instruments shows that the Academy understood generational renewal as an institutional priority. It was no longer enough to hope that young researchers would appear naturally. They had to be attracted, trained, supported, evaluated fairly, and given space to lead.

The deeper meaning of generational renewal is that the Academy's history is not simply transmitted through archives, laws, and institutional names. It is transmitted through people who learn, inherit, criticise, and transform research traditions. Early-career researchers are not only the future of the Academy in a sentimental sense. They are the actors through whom scientific questions change, methods evolve, international networks expand, and public responsibilities are reinterpreted. Their careers reveal whether the Academy's modernisation has created a living institution or only a well-governed structure. The treatment of young researchers therefore becomes a test of the Academy's seriousness. An institution committed to excellence must be committed to those who will define excellence in the next generation.

Thus, generational renewal and support for early-career researchers became a decisive human dimension of the Czech Academy of Sciences' modernisation. The Academy's future depended not only on preserving institutes and funding research, but on building pathways from student interest and doctoral training to postdoctoral independence, group leadership, international mobility, return after career breaks, and long-term scientific responsibility. Instruments such as postdoctoral support, the Otto Wichterle Award, Lumina Quaeruntur, the J. E. Purkyně Fellowship, the Academy of the Future, ERC support, student internships, and university cooperation all contributed to this renewal. At the same time, the process remained marked by tensions between opportunity and precarity, mobility and personal life, evaluation and support, hierarchy and independence, continuity and innovation. Generational renewal is therefore not a separate personnel topic. It is the living mechanism through which AV ČR can remain a modern academy of sciences rather than only the historical successor of earlier institutions.

3. Gender, Leadership, and Institutional Culture

Gender, leadership, and institutional culture form the final and perhaps most human layer of the Academy's modernisation between 1993 and 2025. Earlier parts of this chapter have examined reform, funding, evaluation, European integration, open science, research integrity, and career structures. Yet all these reforms acquire their real meaning only inside the everyday culture of institutes, laboratories, libraries, archives, project offices, and governing bodies. The Academy can have sophisticated evaluation procedures, ambitious European projects, open science policies, and formal career rules, but its future also depends on who is able to enter science, who can remain in it, who becomes visible, who gains authority, who leads, and whose work is recognised. Gender equality is therefore not an auxiliary social theme placed beside "real" science. It is one of the ways in which the Academy's democratic, European, and meritocratic claims are tested in practice. A modern academy of sciences cannot define excellence while ignoring the social conditions under which excellence becomes possible.

The post-1989 transformation created the political and institutional conditions for a new discussion of equality, but it did not automatically remove older inequalities. Under state socialism, women were often present in scientific work, but their representation did not necessarily translate into equal authority, leadership, or recognition. The socialist state promoted women's employment in general terms, yet it rarely dismantled deeper gendered expectations concerning care, domestic work, seniority, decision-making, and professional prestige. After 1989, the return to democracy and market transformation created new freedoms, but also new forms of competition and insecurity. Research careers became more dependent on grants, mobility, publications, evaluation, and international networks. These changes could open opportunities for some women, but they could also intensify inequalities where family responsibilities, career breaks, informal networks, or biased expectations affected career progression. Gender equality in the modern Academy therefore had to be understood not as a simple legacy problem from socialism, but as a structural issue of contemporary research life.

The Czech Republic entered the 2020s with persistent gender imbalances in research. Public discussions and policy analyses repeatedly noted that the proportion of women researchers in Czechia remained among the lowest in the European Union, with women making up less than one third of the research workforce in many statistics and significantly fewer in some fields and senior positions (*Czech Academy of Sciences, 2023*; *European Commission, 2024*; *National Contact Centre for Gender & Science, 2024*). These figures matter because they challenge the common assumption that science is naturally meritocratic once formal barriers disappear. If women are well represented among graduates but become less visible in senior research, leadership, grant success, professorial positions, or decision-making bodies, the problem cannot be explained only by individual choice. It points to institutional cultures, evaluation systems, career timing, care expectations, networks of recognition, and leadership pipelines. The Academy's gender policy therefore belongs to the broader question of how scientific merit is produced, seen, and rewarded.

The Czech Academy of Sciences occupies a distinctive position in this debate because it is both a research-performing institution and the institutional home of important expertise on gender and science. The National Contact Centre for Gender & Science at the Institute of Sociology of the CAS has played a major role in analysing gender equality in Czech research, providing policy advice, supporting institutions, and connecting Czech debates with European gender equality frameworks (*Institute of Sociology of the CAS, n.d.; *Linková, 2023*). This creates an interesting reflexive situation. The Academy is not only the object of gender equality reform; through its own social-scientific expertise, it is also one of the producers of knowledge about the problem. Such reflexivity is important for institutional modernisation. It means that the Academy can draw on internal scholarly capacity to understand and improve its own culture. At the same time, the existence of such expertise creates a responsibility to act on it.

European research policy strongly influenced the institutionalisation of gender equality in Czech research organisations. Horizon Europe made gender equality plans an eligibility criterion for public bodies, research organisations, and higher education institutions participating in the programme (*European Commission, 2021*). This requirement transformed gender equality from a voluntary moral commitment into a practical condition of participation in European research funding. For AV ČR, which had become deeply embedded in European programmes, this was especially important. Gender equality was no longer only an internal personnel question or an ethical aspiration. It became part of the European Research Area's

standards for modern research organisations. This development illustrates how European integration changed not only project funding and evaluation, but also institutional culture.

The Gender Equality Plan of the Czech Academy of Sciences for 2025–2027 represents a significant formal stage in this process. It presents equal opportunities in working conditions, career development, evaluation, and remuneration as fundamental priorities of a modern scientific institution and links gender equality with the improvement of the working environment, institutional culture, and inclusive standards (*Czech Academy of Sciences, 2025*). The plan applies primarily to the CAS Head Office, while CAS institutes, as independent public research institutions, have their own gender equality plans developed in connection with European programme participation (*Czech Academy of Sciences, 2025*). This distinction is important. The Academy is not a single workplace but a complex system of institutes, each with its own legal personality, disciplinary culture, leadership, and personnel structure. Gender equality must therefore operate through both central coordination and institute-level implementation.

The Gender Equality Plan identifies several areas that are highly relevant to the human dimension of modernisation. These include gender balance implementation, work-life balance and organisational culture, gender equality in human resources processes, leadership and decision-making, and measures against gender-based violence and sexual harassment (*Czech Academy of Sciences, 2025*). The breadth of these areas shows that gender equality is not reducible to increasing the number of women in one visible position. It concerns recruitment, promotion, salary, career breaks, leadership training, monitoring, safety, respectful behaviour, and institutional accountability. In this sense, the plan treats gender equality as a systemic cultural issue. It is about the rules and habits through which careers are made possible or difficult.

Work-life balance is one of the most important themes in this policy architecture. The Academy's Gender Equality Plan explicitly recognises organisational culture and work-life balance as key components of an environment in which employees of all genders can build fulfilling careers (*Czech Academy of Sciences, 2025*). This is crucial because research careers often coincide with periods of family formation, care responsibilities, and life decisions that may interrupt or slow linear productivity. In older academic cultures, such interruptions were often treated as individual problems. In a modern research institution, they must be understood as structural conditions that shape equality of opportunity. If the career system assumes uninterrupted mobility, continuous publication, and full-time availability, it quietly favours researchers whose lives fit that model. A humane Academy must therefore design career structures that recognise real biographies.

The Academy's policies concerning maternity and parental leave, return after career breaks, flexible working arrangements, part-time positions, and childcare support are especially relevant here. The Gender Equality Plan mentions school groups established within the Academy, adjusted working hours, part-time positions tailored to family situations, sick days, and a planned return-policy internal programme for researchers and employees coming back from maternity or parental leave (*Czech Academy of Sciences, 2025*). Such measures may appear practical rather than symbolic, but their institutional meaning is substantial. They indicate that excellence should not be defined against care. They also help retain talent that might otherwise be lost at precisely the stage when researchers are becoming experienced,

productive, and capable of leadership. Work-life balance is therefore not a concession to private life; it is a condition of institutional sustainability.

The treatment of career breaks in internal programmes is one of the most important indicators of cultural change. The Academy's Gender Equality Plan states that, in internal programmes supporting excellence or international collaboration, periods of maternity or parental leave, long-term illness, or caring responsibilities are excluded from the calculation of active research time (*Czech Academy of Sciences, 2025*). This approach is important because many excellence schemes use age limits or time-since-PhD rules. Without adjustment, such rules can penalise researchers whose careers have been interrupted for legitimate reasons. By excluding care-related breaks from active research time, the Academy recognises that equal opportunity requires contextual judgement. The researcher's trajectory must be evaluated in relation to the time actually available for research. This is a concrete example of how fairness can be built into meritocratic procedures.

Leadership and decision-making form the second major axis of gender equality. The Academy's Gender Equality Plan identifies balanced gender representation in leadership and decision-making as a priority and calls for monitoring of gender composition in management and governance positions, inclusive leadership training, and mentoring or training to support career progression into leadership roles (*Czech Academy of Sciences, 2025*). This matters because leadership is not simply the final reward for individual excellence. It shapes institutional agendas, resource allocation, recruitment, evaluation, public communication, and the culture of teams. If leadership remains socially narrow, the institution may reproduce hidden assumptions about who belongs at the centre of authority. Balanced leadership brings different experiences and perspectives into governance. It also makes the Academy's claim to equal opportunity more credible.

The history of the Academy's presidency illustrates both continuity and change. Since 1993, the Academy has been led by figures such as Rudolf Zahradník, Helena Illnerová, Václav Pačes, Jiří Drahoš, Eva Zažímalová, and, from 2025, Radomír Pánek (*Czech Academy of Sciences, n.d.*; *Czech Academy of Sciences, 2024*). The presidencies of Helena Illnerová and Eva Zažímalová are important because they made women's leadership visible at the highest level of AV ČR. Yet symbolic visibility at the top cannot by itself resolve gender imbalance throughout the institution. A woman president may represent an important breakthrough, but gender equality also depends on the composition of institute leadership, scientific councils, evaluation panels, grant committees, supervisory boards, department heads, and informal networks of influence. Leadership equality must therefore be analysed as a system, not as a list of exceptional individuals.

The election and appointment of Radomír Pánek for the 2025–2029 term also belongs to this discussion of institutional culture. His programme, as reported by CAS, included support for excellence, competitive salaries, public and political trust in science, support for the next generation of scientists, work-life balance, research ethics, equal opportunities, stronger university partnerships, and greater representation of CAS in European advisory bodies (*Czech Academy of Sciences, 2024*). These priorities show that the leadership agenda of the mid-2020s combined classic research concerns with organisational and cultural questions. Budget, excellence, international presence, ethics, equality, and work-life balance were no longer separate topics. They formed one leadership programme. This integration itself is a sign of the Academy's modernisation.

Institute directors occupy a particularly important position in the gender and leadership structure of AV ČR. The Academy's central bodies can adopt plans, codes, and strategies, but everyday institutional culture is shaped within institutes. Directors influence recruitment, promotion, mentoring, salary distribution, working conditions, conflict resolution, doctoral training, public communication, and openness to reform. They also set the tone for how seriously gender equality and safe working environments are treated. A formal plan can remain weak if institute leadership treats it as administrative compliance. Conversely, committed directors can transform gender equality into a practical tool for improving organisational culture. Leadership is therefore not only representation but implementation.

The issue of inclusive recruitment connects leadership with human resources policy. The Academy's Gender Equality Plan calls for recruitment and career progression procedures based on clear, objective criteria, diverse committees, gender-neutral language in job advertisements, monitoring of gender representation in applications, shortlists, and appointments, and training on unconscious bias for those involved in hiring and promotion (*Czech Academy of Sciences, 2025*). These measures address the fact that inequality often operates through ordinary procedures rather than open discrimination. A job advertisement may discourage some applicants through language or narrow criteria; a selection committee may rely on informal reputation; a career break may be interpreted as lower ambition; a mobility gap may be misunderstood as lack of quality. Inclusive recruitment tries to make these hidden mechanisms visible. It therefore strengthens the credibility of scientific merit.

Unconscious bias is particularly important in research careers because science often sees itself as objective. Researchers are trained to value evidence and method, and this can make academic institutions resistant to recognising bias in their own social processes. Yet hiring, mentoring, promotion, peer review, and leadership selection involve human judgement. Bias can enter through expectations about confidence, availability, mobility, leadership style, parenthood, age, discipline, nationality, or institutional prestige. Training alone cannot eliminate bias, but it can create awareness and provide common language. In an institution such as AV ČR, where peer review and expert judgement are central, awareness of bias is not anti-scientific. It protects the quality of judgement. Inclusive procedures help ensure that excellence is recognised where it actually exists.

Gender equality also intersects with evaluation. If research assessment rewards only uninterrupted productivity, international mobility, high-volume publication, grant accumulation, and visible leadership, it may reproduce inequality even without explicit bias. Researchers with care responsibilities, non-linear careers, interdisciplinary profiles, public-engagement work, or slower forms of scholarship may be disadvantaged. The Academy's movement towards responsible research assessment, including its CoARA commitments and emphasis on qualitative peer review, is therefore relevant to gender equality (*Coalition for Advancing Research Assessment, 2022*; *Czech Academy of Sciences, 2024*). A more plural evaluation culture can recognise diverse contributions and career trajectories. This does not mean lowering standards. It means judging scientific contribution in context. Gender equality and assessment reform therefore reinforce one another.

The Academy's internal excellence programmes also have gender implications. Awards and fellowships such as the Otto Wichterle Award, Lumina Quaeruntur, Praemium Academiae, postdoctoral support, and the Academy of the Future can either reproduce existing inequalities or help correct them. If eligibility rules and evaluation criteria ignore career breaks and care

responsibilities, they may privilege uninterrupted careers. If they actively account for such breaks, as CAS policy increasingly seeks to do, they can support more equitable access to recognition and resources (*Czech Academy of Sciences, 2025*). Lumina Quaeruntur is especially relevant because it supports mid-career researchers, including those returning after parental leave, in establishing their own research groups (*Czech Academy of Sciences, 2025*). This is precisely the stage at which many talented researchers risk being lost. Gender equality therefore becomes part of the Academy's strategy for scientific renewal.

The National Contact Centre for Gender & Science has contributed to this shift by producing analyses, recommendations, training, and public debate around gender equality in research. Its work shows that gender is not only a matter of headcounts but of institutional processes, knowledge production, career systems, and research content (*Institute of Sociology of the CAS, n.d.; *National Contact Centre for Gender & Science, 2024*). The Centre's position within the Institute of Sociology of the CAS is significant because it gives the Academy a strong internal source of expertise in the sociology of science. It also connects AV ČR with European projects and policy networks on gender equality. In this sense, the Academy's gender culture is shaped not only by administrative requirements but by research-based knowledge about inequality. This makes the reform intellectually grounded.

The gender dimension of research content is another important issue. Gender equality in research institutions is not only about who becomes a scientist or leader. It is also about whether research questions, methods, data, and interpretations take gender into account where relevant. In medicine, social sciences, artificial intelligence, urban studies, labour research, environmental policy, and cultural analysis, ignoring gender can produce incomplete or biased knowledge. European policy increasingly stresses the integration of the gender dimension into research and innovation content (*European Commission, 2020*; *European Commission, 2021*). For AV ČR, this issue must be handled with disciplinary sensitivity. Not every research field has the same relation to gender analysis, but where gender is relevant, ignoring it can weaken scientific quality. Gender-sensitive research can therefore be part of excellence, not a political addition to it.

Safe working environment became a major element of institutional culture in the 2020s. The CAS ombudsperson, established under a 2025 Academy Council guideline, is designed to protect CAS employees, students, and external collaborators from undesirable behaviour and to support a safe, fair, and respectful working environment (*Czech Academy of Sciences, 2025*). The ombudsperson's role includes awareness-raising, assistance and advice, examination of reports, proposals for measures, and preventive work, while maintaining independence, confidentiality, impartiality, and protection against disadvantage for those who contact the office (*Czech Academy of Sciences, 2025*). This mechanism is important because institutional culture cannot be improved only through declarations. People need safe channels to raise concerns. The ombudsperson gives the Academy a practical instrument for addressing power imbalances and harmful behaviour.

Measures against gender-based violence and sexual harassment are especially important in research organisations because academic environments often contain hierarchical dependence. Doctoral students, postdoctoral researchers, project staff, foreign researchers, and junior employees may depend on supervisors, principal investigators, or directors for contracts, recommendations, publications, visas, and future positions. This dependence can make it difficult to report misconduct. The Gender Equality Plan therefore emphasises

prevention, awareness-raising, clear reporting procedures, confidentiality, protection of parties involved, and a culture of zero tolerance (*Czech Academy of Sciences, 2025*). Such measures are not only about individual safety. They protect the integrity of research environments. Science cannot flourish where fear, humiliation, or abuse of power are normalised.

The Code of Conduct and Code of Ethics provide another layer of institutional culture. The Gender Equality Plan notes that the Code establishes principles of respect, non-discrimination, prevention of violence, harassment and bullying, including gender-based violence, as well as honesty, responsibility, fairness, transparency, avoidance of conflicts of interest, and special responsibilities for those in leadership positions (*Czech Academy of Sciences, 2025*). These principles connect gender equality with research integrity. A respectful workplace is not separate from good science; it is one of its conditions. Harassment, discrimination, and bullying damage trust, silence criticism, distort mentoring, and push talented people out of research. Ethical conduct therefore includes the social environment of knowledge production.

Institutional culture is also shaped by the distribution of informal authority. Formal leadership positions matter, but academic life is also governed by reputations, networks, invitations, editorial roles, conference panels, project leadership, authorship patterns, and access to senior mentors. Gender imbalance may persist even when formal rules are equal because informal recognition remains uneven. Women and other underrepresented researchers may be invited less often to speak, cited less frequently, nominated less often for awards, or excluded from influential networks. The Academy's policies on monitoring, mentoring, leadership training, and evaluation can help address these hidden structures. Yet such change requires sustained attention. Institutional culture is reproduced through everyday choices, not only through formal appointments.

Mentoring is one of the most important tools for changing this culture. The Gender Equality Plan calls for mentoring and training initiatives to support career progression into leadership roles (*Czech Academy of Sciences, 2025*). Mentoring can help early- and mid-career researchers understand institutional rules, apply for grants, prepare for leadership, manage teams, and navigate evaluation. It can also compensate for unequal access to informal networks. However, mentoring must be designed carefully. It should not become a substitute for structural change, nor should it place the burden of adaptation only on those disadvantaged by existing systems. Effective mentoring works together with transparent recruitment, fair evaluation, leadership accountability, and resource support. It helps individuals succeed while institutions change.

The relationship between gender equality and generational renewal is especially close. Younger researchers often bring different expectations concerning work-life balance, respectful communication, leadership style, equality, open science, and international collaboration. They may be less willing to accept old hierarchical cultures as natural. At the same time, early-career researchers are often more precarious and therefore less able to challenge problematic behaviour. This creates a tension. Generational renewal can help transform institutional culture, but only if young researchers are protected and supported. The Academy's ombudsperson, career-development programmes, gender equality plans, and responsible assessment reforms all contribute to this protection. Without them, the burden of cultural change falls unfairly on those with the least power.

Leadership style itself became part of modernisation. The older model of the powerful institute director or senior professor, whose authority was rarely questioned, is less compatible with contemporary expectations of transparent governance, team science, equality, and international accountability. Modern leadership requires scientific vision, but also communication, mentoring, conflict management, ethical awareness, administrative competence, and attention to diversity. CAS evaluation increasingly considers institute strategy, governance, leadership, and working environment, not only publications or grants (*Czech Academy of Sciences, 2026*). This broadening is important. It means that leadership is judged not only by scientific prestige but by the capacity to create conditions in which others can do good work. Institutional culture thus becomes part of institutional quality.

The Academy Assembly and other governing bodies also matter for institutional culture. The CAS is governed through a self-governing structure that includes the Academy Assembly, Academy Council, President, and Council for Sciences; members of Academy bodies are elected for four-year periods, and the Assembly includes representatives of institutes as well as universities, state administration, business circles, and public life (*Czech Academy of Sciences, n.d.*). This structure can support plural representation, but it also raises questions about who participates, whose voices are heard, and how diversity is reflected in decision-making. Gender equality in leadership is therefore not limited to the presidency or institute directors. It concerns the composition and culture of all deliberative and executive bodies. Democratic scientific governance requires attention to representation as well as procedure.

The decentralised structure of AV ČR makes implementation complex. Each institute has its own disciplinary culture, leadership history, personnel profile, and gender composition. Some fields, such as certain branches of biology, social sciences, or humanities, may have different gender patterns from physics, engineering, mathematics, or informatics. A uniform central policy may not address the specific barriers present in each field. At the same time, leaving everything to institute autonomy risks uneven standards. The Academy must therefore combine central principles with local responsibility. Institute-level gender equality plans, monitoring, training, and ombudsperson mechanisms help translate general values into concrete settings. This is one of the characteristic challenges of governing a modern academy of institutes.

The role of data collection and monitoring is essential. The Gender Equality Plan calls for collecting and regularly evaluating gender-disaggregated data on employees, positions, and organisational bodies, and for preparing periodic reports on implementation (*Czech Academy of Sciences, 2025*). Data do not solve inequality by themselves, but without data inequality remains easy to deny. Monitoring can reveal where women and men are positioned in the hierarchy, whether recruitment processes are balanced, whether promotion rates differ, whether leadership remains skewed, and whether measures are producing change. Data also support accountability. A plan without monitoring can become symbolic; a plan with monitoring can become a management tool. Transparency in gender equality therefore parallels transparency in research evaluation.

At the same time, gender data must be interpreted carefully. Numbers can show imbalance, but they cannot fully explain its causes. A low proportion of women in a field may reflect educational pipelines, hiring practices, workplace culture, care expectations, international mobility requirements, evaluation criteria, or broader social stereotypes. Leadership imbalance may result from accumulated disadvantage over decades, not only from current

discrimination. A serious institution must therefore combine quantitative monitoring with qualitative understanding. Surveys, interviews, focus groups, ombudsperson experience, and analysis of career trajectories can all deepen the picture. Gender equality policy requires the same methodological sophistication that the Academy demands in research evaluation. Counting is necessary, but interpretation is indispensable.

Gender equality also intersects with international competitiveness. Research organisations that offer safe, inclusive, family-compatible, and transparent working environments are better able to attract and retain talent. In the European Research Area, excellent researchers can choose among institutions. Salary and infrastructure matter, but so do organisational culture, leadership, fairness, and support for life-course transitions. The Academy's Gender Equality Plan therefore belongs to talent policy. It helps define CAS as a modern employer capable of competing for researchers in a European labour market. Conversely, if the Academy were perceived as hierarchical, opaque, or unsafe, it would lose talent regardless of formal scientific excellence. Institutional culture is thus a component of competitiveness.

The issue of gender equality also affects public trust. AV ČR presents itself as a leading public research institution serving Czech society and national culture while advancing knowledge at the international level (*Czech Academy of Sciences, n.d.*). A public institution that claims to serve society must reflect democratic values in its own organisation. This does not mean that every imbalance can be corrected immediately, but it does mean that the institution must recognise problems and work systematically to address them. Gender equality, safe working environments, and inclusive leadership strengthen the Academy's civic legitimacy. They show that modernisation is not only technological or administrative, but ethical and social. The Academy's public authority depends partly on whether its internal culture matches its public mission.

The broader Czech policy context also shaped the Academy's reforms. The Czech Republic adopted national strategies and action plans on gender equality in research, while European and national funding bodies increasingly required institutional gender equality plans. The Czech Science Foundation introduced the requirement to report a gender equality plan as part of grant-call participation from 2023 (*Czech Academy of Sciences, 2023*). Such funding conditions changed institutional incentives. Research organisations could no longer treat gender equality as optional public relations. It became connected with eligibility, evaluation, and competitiveness. This mirrors earlier developments in open science and research assessment: values become institutionally effective when linked to rules, funding, and accountability.

The Institute of Sociology's own Gender Equality Plan illustrates how institute-level plans can address the specific environment of a CAS workplace. It identifies work-life balance, organisational culture, leadership, decision-making, recruitment, career development, research content, and protection from harassment among key concerns (*Institute of Sociology of the CAS, 2022*). Other CAS institutes have developed their own plans in response to European requirements and internal needs. This institute-level diversity is important because gender equality cannot be implemented effectively only through central documents. Each institute must confront its own patterns of hierarchy, field-specific career expectations, leadership composition, and workplace climate. The central Academy can set standards, but the lived culture of equality is local.

The relationship between gender equality and disciplinary diversity is especially complex. In some STEM fields, the main problem may be the low share of women in the talent pipeline and senior positions. In humanities and social sciences, women may be more numerous but still underrepresented in professorial ranks, directorships, major grants, or formal authority. In technical and experimental fields, mobility, laboratory culture, long hours, and infrastructure leadership may create particular barriers. In archival or humanities fields, precarious contracts and undervalued national-language work may affect career progression. The Academy's broad structure means that gender equality must be translated into different disciplinary languages. A one-size-fits-all approach risks missing the mechanisms that operate in specific fields.

Institutional culture also includes the relationship between scientific and administrative staff. Gendered patterns of work can appear not only among researchers but also in support roles, management, communication, project administration, libraries, and technical services. Women may be overrepresented in less visible organisational labour and underrepresented in scientific leadership. A modern Academy must therefore analyse the whole institution, not only research posts. The Gender Equality Plan's attention to CAS Head Office is important here because administrative and governance structures shape the conditions of research. Equal opportunity in an academy of sciences includes researchers, managers, administrators, students, and external collaborators. The social ecology of science is broader than the laboratory.

The creation of the ombudsperson also highlights the importance of trust in institutional procedures. People will not report undesirable behaviour if they believe nothing will happen, if they fear retaliation, or if procedures are opaque. The CAS guideline states that a person who contacts the ombudsperson cannot be penalised or disadvantaged for doing so and that the ombudsperson follows principles of independence, safety, transparency, prevention, empathy, participation, confidentiality, and impartiality (*Czech Academy of Sciences, 2025*). These principles are essential because safe working environment policies succeed only when people trust them. A paper mechanism without trust is ineffective. The ombudsperson's work therefore belongs to the deeper task of rebuilding institutional confidence.

The cultural significance of these reforms becomes clearer when compared with the Academy's earlier history. The socialist Academy was marked by formal hierarchy, ideological pressure, and limited room for open criticism. Normalisation intensified the culture of caution, conformity, and dependence. The democratic Academy rebuilt autonomy, but some hierarchical habits and informal power structures could survive beyond political transformation. Gender equality, ombudsperson mechanisms, transparent recruitment, inclusive leadership, and safe workplace policies therefore represent a second-order democratisation. They do not concern the macro-political relationship between science and the state alone. They concern democracy inside the institution: voice, dignity, fairness, representation, and protection from abuse of power. This is why institutional culture belongs at the end of the chapter on modernisation.

The Academy's gender and culture reforms are still incomplete, and they should not be romanticised. Plans, committees, data collection, training, and ombudsperson offices do not automatically change deep habits. Some measures may remain formal if leadership is passive. Some researchers may perceive gender equality as bureaucracy rather than as part of scientific quality. Some institutes may progress faster than others. The broader Czech research system still faces low female representation in many research fields and senior positions. These

difficulties do not invalidate the reforms. They show that cultural modernisation is slower than legal or administrative change. It requires persistence, leadership, monitoring, and the willingness to discuss uncomfortable issues.

By 2025, however, it is clear that gender, leadership, and institutional culture had moved from the margins to the centre of Academy governance. They appeared in the Gender Equality Plan, Code of Conduct, ombudsperson guidelines, research integrity discussions, career-development policies, evaluation reforms, and presidential priorities. They also intersected with European funding requirements, responsible research assessment, open science, and early-career support. This convergence is historically important. It shows that the modern Academy no longer understands excellence as something produced independently of working conditions. Scientific quality depends on institutional culture. A respectful, inclusive, transparent, and supportive Academy is better able to produce, retain, and recognise excellent research.

Thus, gender, leadership, and institutional culture complete the picture of the Czech Academy of Sciences' modernisation between 1993 and 2025. The Academy's transformation was not only legal, financial, evaluative, European, or digital; it was also social and cultural. Gender equality policies, leadership monitoring, inclusive recruitment, work-life balance measures, support for return after career breaks, ombudsperson mechanisms, codes of conduct, and attention to safe working environments all show that AV ČR increasingly understood scientific excellence as inseparable from fair institutional conditions. The process remained uneven and unfinished, but its direction was clear. The Academy moved from a post-socialist struggle for autonomy towards a European model of research governance in which autonomy, equality, integrity, leadership responsibility, and public trust belong together. In this sense, the human dimension of modernisation is not an appendix to the institutional history of the Academy. It is the condition under which the Academy can remain a living, credible, and future-oriented scientific institution.

Part Five.

Research Achievements and Scientific Directions of the Modern Academy

Chapter Ten

Natural Sciences, Mathematics, and the Physical Sciences

Physics and the Study of Matter

1. Condensed Matter, Optics, Plasma, and High-Energy Research

Physics within the Czech Academy of Sciences occupies a special place in the modern history of Czech science because it links two very different meanings of scientific work: the investigation of nature at its most fundamental levels and the construction of institutional capacities that only a mature research system can sustain. In this sense, the study of matter was never merely one disciplinary field among others. It was a domain in which the Academy tested its ability to preserve long-term expertise, operate demanding instruments, educate generations of researchers, and remain connected to the international scientific frontier. The Academy's physical sciences developed across several layers: condensed matter and solid-state physics, optics and laser science, plasma physics and fusion research, nuclear physics, particle physics, and astroparticle physics. These layers did not form a single linear narrative, but together they created one of the most technically complex and internationally visible segments of the Czech research system. Their development also reveals the broader institutional logic of the Academy after the socialist period: continuity of expertise, reform of governance, internationalisation of infrastructure, and the gradual move from nationally enclosed research to participation in European and global "big science" (*Akademie věd České republiky, n.d.*; *Fyzikální ústav AV ČR, n.d.*).

The organisation of physics in the Academy reflected the wider structure of the institution. Within the research area of Mathematics, Physics, and Earth Sciences, physics was placed alongside mathematics, computer science, astronomy, nuclear physics, and information theory, while applied physics included institutions concerned with photonics, materials, plasma physics, scientific instruments, mechanics, and thermomechanics (*Akademie věd České republiky, n.d.*). This distribution is important because it shows that physics in the Czech Academy was never confined to one institute or one methodological culture. It extended from abstract theoretical modelling to accelerator-based experiments, from the microstructure of solids to the behaviour of plasma, and from the physics of optical systems to cosmic particles arriving from outside the Solar System. The institutional geography of Czech physics therefore mirrored the intellectual geography of modern physics itself: matter could be studied as a crystal lattice, as a quantum system, as ionised gas, as nuclear structure, as elementary particles, or as radiation detected by sophisticated instruments. The Academy's strength lay precisely in this plurality, which allowed it to combine depth in specialised fields with flexibility across disciplinary borders.

The Institute of Physics of the Czech Academy of Sciences became the principal institutional centre of this landscape. Its origins in the 1950s placed it within the first great wave of post-war and early socialist institutionalisation of science, when physics was treated as a strategic field for industrial modernisation, technological sovereignty, and ideological prestige. Yet the

Institute's later history cannot be reduced to the administrative logic of state socialism. Over time, it accumulated scientific schools, experimental traditions, technical workshops, international contacts, and disciplinary cultures that outlived the political order in which they had been assembled. Its research profile came to include elementary particle physics, condensed matter and solid-state physics, optics, plasma physics, and laser physics, making it a broad rather than narrowly specialised physical institute (*Fyzikální ústav AV ČR, n.d.*). This breadth was institutionally significant: it allowed the Institute to act both as a custodian of inherited Czechoslovak physical research and as a platform for the new international projects of the post-1989 era.

Condensed matter physics formed one of the most durable lines of this development. Its importance lay in the fact that it connected fundamental questions about the structure of matter with problems that had direct technological resonance. The behaviour of electrons in solids, the formation of magnetic and dielectric properties, the physics of surfaces and thin films, the properties of crystals, and the emergence of new functional materials were not only theoretical subjects. They were also connected to electronics, energy technologies, sensors, optoelectronics, metallurgy, and later nanotechnologies. In the Academy, condensed matter research was therefore a field in which the distinction between "basic" and "applied" science was often porous. Researchers could move from the study of fundamental mechanisms to the design or characterisation of materials without abandoning the identity of basic research. This permeability became especially important after the transformation of the 1990s, when public research institutions had to demonstrate international quality and social relevance without reducing science to short-term utility.

The Czechoslovak tradition in solid-state and condensed matter physics had been built under conditions that were often politically constrained but technically ambitious. Like many areas of scientific work in the socialist period, it benefited from stable institutional employment, long-term laboratory development, and state interest in technically useful fields. At the same time, it suffered from restrictions on mobility, limited access to some instruments, political interference in careers, and asymmetries in international exchange. This double legacy shaped the post-socialist Academy. The question after 1989 was not whether the older scientific schools should simply be rejected or preserved unchanged. The real issue was how to separate durable expertise from the administrative and ideological forms that had surrounded it. Condensed matter physics was one of the fields in which this separation could be relatively successful because its objects of study, methods, and international standards were less directly ideological than those of the social sciences. Nevertheless, its institutional renewal still required new funding patterns, competitive projects, publication strategies, and stronger integration into European scientific networks.

The intellectual appeal of condensed matter physics also came from its ability to make the ordinary extraordinary. Matter in this field was not a passive substance but an organised system whose macroscopic properties arose from microscopic interactions. A crystal, a semiconductor, a thin film, a magnetic material, or a liquid crystal could become a world of phase transitions, defects, collective excitations, quantum effects, and emergent behaviour. This gave the field a conceptual richness that helped to bridge experimental measurement and theoretical interpretation. In the Academy's environment, such research required stable laboratories, highly trained technical staff, access to characterisation instruments, and long research cycles that did not fit easily into short political or commercial timelines. The Academy's institutional form was well suited to this kind of work. It could maintain research

continuity in areas where universities alone often lacked the necessary infrastructure and where industry was interested mainly in later stages of application.

The study of materials was closely connected to this condensed matter tradition. The Academy's physical sciences included not only the Institute of Physics but also specialised institutes concerned with materials, photonics, scientific instruments, and related areas of applied physics. This institutional constellation allowed the Czech research system to treat materials not simply as industrial inputs but as complex physical systems. In this respect, the Academy's work anticipated a broader European tendency in which materials science became a meeting place for physics, chemistry, engineering, and computation. The analysis of defects, surfaces, nanostructures, magnetic systems, optical properties, and mechanical behaviour created a common scientific language across institutes. This was especially important for a country whose industrial history had long included machinery, glass, optics, electronics, metallurgy, and precision instrumentation. Physics did not stand outside this economic and technological culture; it gave it deeper analytical foundations.

Optics represented another major line of continuity and transformation. In Czech scientific culture, optics had older roots in precision instruments, glass technologies, microscopy, spectroscopy, and astronomical observation. Within the Academy, modern optics developed into a field that connected classical optical knowledge with quantum optics, nonlinear optics, laser physics, photonics, and the physics of surfaces and layers. The institutional significance of optics was that it linked local technical traditions to the most advanced experimental practices of contemporary science. Optical methods became indispensable in condensed matter research, plasma diagnostics, biological imaging, astronomical observation, and high-energy astrophysics. This meant that optics was both a discipline and an enabling technology. It gave the Academy tools with which other sciences could see, measure, control, and interpret phenomena otherwise inaccessible to ordinary observation.

The growth of laser research transformed the scale and ambition of Czech optics. Lasers altered the physical sciences because they made it possible to concentrate energy, measure ultrafast processes, generate secondary radiation, manipulate matter, and create experimental conditions that had previously been inaccessible. In the Czech Academy, laser physics became a bridge between traditional optical expertise and European-scale infrastructure. This was not simply a matter of acquiring expensive devices. It required a new culture of project management, safety, engineering, international user access, and interdisciplinary cooperation. The emergence of large laser facilities near Prague showed that the Czech research system could move from participation in external infrastructures to hosting infrastructure of European significance. In this sense, optics became one of the clearest examples of the Academy's post-socialist institutional modernisation.

The ELI Beamlines facility in Dolní Břežany symbolised this change. As part of the Extreme Light Infrastructure, it placed Czech laser science within a distributed European research infrastructure devoted to high-power, high-intensity, and ultrashort-pulse laser systems (*ELI Beamlines, n.d.*; *Extreme Light Infrastructure ERIC, n.d.*). The importance of ELI Beamlines for the Academy and for Czech science was not limited to the prestige of hosting a major facility. It changed the relationship between national research and international scientific users. A laboratory of this type is not built only for local teams; it is designed as a site where international communities can conduct experiments in physics, materials science, chemistry, life sciences, and laboratory astrophysics. For the Academy, this meant entering a regime in

which scientific reputation depended not only on publications but also on the reliability, accessibility, and originality of infrastructure. The facility thus represented a new institutional language: user operation, beamtime, international calls, engineering support, and integration with European research policy.

ELI Beamlines also shows how the study of matter has expanded beyond traditional categories. High-intensity lasers can generate X-rays, accelerated particles, and extreme states of matter; they can support ultrafast imaging, plasma acceleration, materials investigation, and experiments relevant to astrophysical and nuclear processes. This makes the laser facility a meeting point of optics, plasma physics, materials science, accelerator physics, and applied research. The very concept of "matter" becomes dynamic: matter is no longer only observed in equilibrium but driven, excited, compressed, ionised, and transformed on ultrashort timescales. Such research requires conceptual imagination as well as technical coordination. It also requires an institution capable of sustaining long-term scientific risk. The Academy's participation in this field therefore reflected not merely a successful infrastructure project but a deeper shift in the Czech scientific system towards experimental platforms that can create new research questions rather than only answer inherited ones.

Plasma physics formed a further essential component of the Academy's physical sciences. Its institutional centre was the Institute of Plasma Physics of the Czech Academy of Sciences, which became the leading Czech research institution in the field of nuclear fusion (*EUROfusion, n.d.*). Plasma research is especially revealing because it lies at the intersection of fundamental physics, energy policy, materials engineering, diagnostics, and international cooperation. The behaviour of high-temperature plasma cannot be understood without sophisticated theory, modelling, measurement, and experimental control. At the same time, the promise of fusion energy gives the field a strategic significance that goes far beyond ordinary laboratory work. In the Czech case, plasma physics therefore connected the Academy to one of the most ambitious long-term technological projects of modern science: the effort to make controlled thermonuclear fusion a practical energy source.

The COMPASS tokamak became the most visible symbol of this tradition. Its operation in Prague placed Czech researchers within the European fusion community and provided a training ground for scientists, engineers, and students. The machine was not merely a device for local experiments; it was part of a wider European effort to understand plasma confinement, magnetic field errors, plasma edge behaviour, and the problems relevant to ITER and later DEMO. During its years of operation, COMPASS produced a large number of high-temperature plasma discharges and helped to bring Czech fusion research into the European top tier (*Akademie věd České republiky, 2021*). This mattered institutionally because it showed that a comparatively small national research system could make meaningful contributions to a field dominated by large international programmes. The value of COMPASS lay not only in its scale but in its specificity, diagnostic capacities, and ability to address problems relevant to larger machines.

The transition from COMPASS to COMPASS-U further illustrates the Academy's movement from inherited infrastructure to deliberately strategic infrastructure. COMPASS-U was conceived as a high-magnetic-field tokamak with plasma geometries relevant to ITER and DEMO, designed to address key challenges of fusion research (*Institute of Plasma Physics of the CAS, n.d.*). Its projected characteristics, including high magnetic field, high plasma density, advanced plasma configurations, and a well-diagnosed divertor environment, point to a

research agenda focused on questions that remain central to the future of fusion energy. This is precisely the kind of project that reveals the Academy's distinctive role. It is not a commercial prototype, nor is it a purely educational device. It is a research infrastructure intended to occupy a specialised place in the European fusion ecosystem. Such a role requires scientific credibility, engineering capacity, political support, and long-term institutional commitment.

Plasma research in the Academy was not limited to tokamak physics. The field also included laser plasma, low-temperature plasma, plasma chemistry, plasma–material interaction, and optical diagnostics. These areas connected high-energy experimental physics with materials science, surface treatment, environmental technologies, and industrial processes. They also demonstrated that plasma is not a single object but a family of physical states and applications. High-temperature plasma research belongs to the world of fusion, magnetic confinement, and extreme energy conditions. Low-temperature plasma and plasma chemistry, by contrast, can be linked to material modification, thin films, chemical processes, and technological innovation. This diversity made plasma physics one of the most interdisciplinary parts of the Academy's physical sciences. It also allowed the Academy to maintain a balance between long-term fundamental projects and research with more immediate technological relevance.

High-energy research introduced another scale of matter: the scale of elementary particles, cosmic rays, and nuclear processes. Within the Institute of Physics, elementary particle physics and astroparticle physics connected Czech teams to large international collaborations, where national scientific identity is expressed through participation in detectors, data analysis, instrumentation, and theoretical interpretation rather than through isolated laboratories. This form of research is institutionally demanding because no single medium-sized country can reproduce the full infrastructure of particle physics. Instead, the Academy had to act through collaboration, specialisation, and credibility. Its scientists contributed to international experiments by bringing expertise in detector technologies, optics, electronics, data processing, and theoretical analysis. The resulting scientific culture differed from classical national laboratory work. It was distributed, multilingual, project-based, and dependent on long-term trust among institutions.

The Nuclear Physics Institute of the Czech Academy of Sciences added a further dimension to this high-energy and nuclear landscape. Its roots go back to the founding of a nuclear physics institute in Řež in 1955 as a basic Czechoslovak institution in nuclear fields, followed by institutional reorganisation in 1972 and later incorporation into the Czech Academy of Sciences after 1993 (*Nuclear Physics Institute of the CAS, n.d.*). This history is a compact example of continuity and rupture in Czech science. Nuclear physics was shaped by the priorities of the socialist state, by the development of nuclear energy, by Cold War science, and by the strategic value assigned to nuclear knowledge. Yet the basic-research component survived institutional separations and political transformation. In the post-socialist Academy, the Nuclear Physics Institute continued work in experimental and theoretical nuclear physics, intermediate-energy and heavy-ion physics, nuclear analytical methods, dosimetry, material research, and interdisciplinary applications.

Nuclear physics was also one of the fields where the Academy's expertise crossed the boundary between fundamental science and public responsibility. Research on nuclear reactions, ionising radiation, dosimetry, neutron methods, and material analysis had obvious relevance for energy, medicine, environmental monitoring, archaeology, and radiation

protection. This did not make the field merely applied. Rather, it placed basic nuclear knowledge within a wider social and technical framework. The Academy could provide expertise where the state, industry, health institutions, and cultural heritage organisations needed reliable scientific judgement. In this sense, nuclear physics illustrates an important feature of the Academy's institutional identity: it was not a university department, a ministry laboratory, or a company research unit, but a public research institution capable of combining independent inquiry with long-term national expertise.

Astroparticle physics extended high-energy research beyond terrestrial laboratories. Czech participation in infrastructures such as the Cherenkov Telescope Array and the Pierre Auger Observatory linked the Academy to the study of high-energy cosmic rays and gamma rays. These fields depend on global observational networks, advanced optics, atmospheric monitoring, detector systems, and large-scale data analysis. Czech researchers contributed through optical technologies, mirror development, camera systems, atmospheric monitoring, and scientific participation in international collaborations (*Research Infrastructure CTA-CZ, n.d.*). This is another example of how inherited Czech strengths in optics and instrumentation could be translated into contemporary global science. The study of the Universe at high energies thus became connected to very concrete national competencies: precision engineering, optical surfaces, calibration, and data interpretation.

The Academy's participation in high-energy and astroparticle research also changed the meaning of scientific autonomy. In the 19th-century learned society or the early national academy, autonomy often meant the ability of scholars to pursue knowledge without immediate political or ecclesiastical control. In the 20th-century Academy, especially under state socialism, autonomy was repeatedly constrained by ideology, administrative hierarchy, and state planning. In contemporary high-energy research, however, autonomy has a more complex meaning. It requires the ability to enter international collaborations on equal scientific terms, to maintain funding for long projects, to protect expert judgement within large institutional consortia, and to preserve national scientific capacity without retreating into isolation. The Academy's role in particle, nuclear, plasma, and laser physics therefore demonstrates a modern form of autonomy: not solitude, but competent participation in networks too large for any one institution to dominate.

The physical sciences also reveal the importance of instrumentation as a form of knowledge. In many historical narratives, scientific ideas are treated as primary and instruments as auxiliary. The Academy's experience suggests a more integrated picture. Instruments do not merely record nature; they define what can be observed, measured, stabilised, compared, and imagined. A tokamak, a laser beamline, a detector array, a neutron facility, an optical laboratory, or a surface-analysis instrument is part of the intellectual architecture of science. This was especially true in the Czech case, where long traditions of precision engineering, optics, materials expertise, and experimental craftsmanship supported participation in advanced physical research. The Academy's institutes were therefore not only places where theories were tested, but places where the material culture of science was produced and maintained.

The post-1989 transformation changed the institutional environment in which these fields operated. Under the Czechoslovak Academy of Sciences, physics had enjoyed a privileged status among natural sciences, but it was also embedded in a system of central planning, restricted mobility, and politically mediated institutional hierarchies. After 1989, the successor

Academy had to operate in a very different world: competitive grants, international evaluation, publication metrics, European framework programmes, public research institution status, and growing expectations of innovation and technology transfer. The physical sciences were relatively well positioned for this transition because many of their standards were already international and because experimental cooperation across borders had never been entirely absent. Yet the transition still required deep adaptation. Institutes had to modernise equipment, renew leadership cultures, attract younger researchers, publish more visibly, compete for European funding, and justify costly infrastructure to public authorities.

This transformation also altered the relationship between the Academy and universities. In physics, the Academy could not function as a closed research estate. It depended on doctoral students, joint laboratories, university teaching, shared appointments, and collaboration with faculties in Prague, Brno, Olomouc, and elsewhere. Conversely, universities benefited from access to Academy laboratories, instruments, and research groups that often exceeded ordinary teaching infrastructure. This relationship was particularly important in fields such as condensed matter, optics, plasma physics, nuclear physics, and particle physics, where training cannot be separated from participation in real experimental work. The Academy thus became a national reservoir of advanced research training. It helped to reproduce scientific elites not only by employing researchers but also by providing environments in which young scientists could learn how contemporary physics is actually practised.

The cultural meaning of physics within the Academy should not be overlooked. Physics has often carried a symbolic weight disproportionate to its institutional size because it is associated with the deepest questions about nature and with the most visible forms of scientific modernity. In the Czech context, this symbolism was intensified by the history of a small nation seeking intellectual parity with larger European cultures. Participation in modern physics demonstrated that Czech science was not provincial, derivative, or merely national in scope. It belonged to a universal language of experiment, mathematics, and theory. At the same time, the Academy's physical sciences remained embedded in local institutions, Czech technical traditions, and national educational structures. The result was a productive tension between universality and locality: Czech physics was international in its standards but national in its institutional responsibility.

Condensed matter, optics, plasma, and high-energy research therefore form more than a catalogue of disciplines. They show how the Academy learned to operate across scales: from electrons in solids to plasma in magnetic confinement, from optical surfaces to cosmic particles, from laboratory materials to European infrastructures. They also show how institutional history is written through instruments, laboratories, research schools, and collaborative networks. The Academy's physical sciences preserved important Czechoslovak continuities, but they did not remain trapped in inherited forms. They were reshaped by European integration, large infrastructures, competitive funding, and the growing importance of interdisciplinary research. Their development illustrates a broader theme of the Academy's modern history: the survival of scientific autonomy depended not on institutional immobility but on the capacity to transform inherited expertise into new forms of international relevance.

Thus, condensed matter physics, optics, plasma physics, and high-energy research demonstrate the Academy's role as a long-term custodian of advanced scientific capacity in the Czech lands. These fields connected the material, conceptual, and institutional dimensions of science: they required theoretical imagination, experimental discipline,

technical infrastructure, public funding, and international trust. They also reveal why the history of the Academy cannot be written only as a history of administrative reforms or political regimes. It must also be written through the laboratories where matter was studied, through the instruments that made invisible phenomena measurable, and through the research communities that carried Czech science from the enclosed structures of state socialism into the open but demanding networks of European and global science. In this sense, the physical sciences were not a specialised appendix to the Academy's history; they were one of the central arenas in which the modern Czech Academy of Sciences defined its intellectual authority, institutional autonomy, and international standing.

2. Research Infrastructures and International Collaborations

The development of physics in the Czech Academy of Sciences cannot be understood without the history of research infrastructures. In the modern physical sciences, laboratories are not merely places where individual scholars conduct experiments; they are organised environments in which machines, technical staff, data systems, international users, safety regimes, funding bodies, and long-term scientific agendas come together. This is especially true for fields such as laser physics, plasma research, particle physics, nuclear physics, materials science, and astroparticle physics, where the central instruments are too complex and too costly to be treated as ordinary institutional equipment. The Academy's role in this domain was therefore not simply to host institutes, but to maintain capacities that allowed Czech science to participate in the contemporary infrastructure-based form of knowledge production. In this respect, the post-socialist transformation of the Academy was not only administrative or financial. It was also infrastructural. The ability to build, operate, upgrade, and open large research facilities became one of the main indicators of whether the Academy could remain a serious actor in European science.

Research infrastructure changed the scale at which Czech physics operated. Earlier traditions of laboratory physics depended on individual groups, specialised instruments, and relatively stable institutional schools. These elements remained important, but they increasingly became embedded in larger systems of cooperation. A condensed matter physicist might require nanofabrication tools, cryogenic measurements, electron microscopy, synchrotron access, or high-field magnetic measurements. A nuclear physicist might depend on accelerators, neutron sources, detectors, radiochemical laboratories, and dosimetry facilities. A plasma physicist might need tokamak operation, heating systems, diagnostics, high-performance computing, and access to European machines. A particle physicist might work through CERN experiments, distributed data processing, detector development, and long-term international consortia. The Academy's physical sciences therefore moved from a model of institutes with laboratories to a model of institutes embedded in infrastructure ecosystems.

This shift was closely connected with the emergence of national and European infrastructure policy. The Czech Republic gradually developed a system of large research infrastructures, coordinated through national roadmaps and linked to European frameworks such as ESFRI, ERICs, and European framework programmes. The Roadmap of Large Research Infrastructures of the Czech Republic for the years 2023–2026 placed physical sciences and engineering among the central domains of national infrastructure strategy, including Czech participation in ELI, CERN, CTAO, ESS, FAIR, EuPRAXIA, and other major European or global facilities (*Ministry*

of Education, Youth and Sports, 2024). This framework matters historically because it shows that advanced physics was no longer financed only as the internal work of one institute. It became part of national science policy, European integration, and international competition for scientific visibility. The Academy's institutes had to act not only as research bodies, but also as infrastructure operators, national nodes, coordinators, and partners in transnational systems.

The Institute of Physics of the Czech Academy of Sciences became one of the main institutional platforms for this infrastructure turn. Its position was strengthened by the breadth of its research profile, which included particle physics, condensed matter physics, solid-state physics, optics, plasma physics, and laser physics (*Fyzikální ústav AV ČR, n.d.*). This breadth allowed the Institute to participate in several infrastructure regimes at once. It could host or co-develop laser facilities, contribute to materials and nanotechnology platforms, coordinate Czech participation in high-energy experiments, and support astroparticle research. Such an institution could not function as a narrow disciplinary institute. It had to become a mediator between national scientific priorities, European projects, industrial partners, universities, and international user communities. Its history therefore illustrates a broader change in the Academy: the strongest institutes increasingly became nodes in networks rather than isolated centres of excellence.

The laser infrastructures around Prague and Dolní Břežany demonstrate this transformation most clearly. ELI Beamlines became one of the most visible Czech scientific infrastructures of the post-1989 period. As part of the Extreme Light Infrastructure, it connected Czech laser science with a European user facility devoted to high-power, high-intensity, and ultrashort-pulse laser systems (*ELI ERIC, n.d.*; *ELI Beamlines, n.d.*). Its significance was not limited to the possession of powerful lasers. It represented a new institutional form in which the Czech research system hosted an infrastructure designed for international scientific users. This required governance, technical reliability, safety protocols, user access rules, beamtime allocation, data management, engineering support, and international evaluation. The Academy's participation in this process marked a transition from national laboratory culture to the culture of European big science.

ELI Beamlines also transformed the relationship between Czech physics and international scientific agendas. High-intensity laser systems allow researchers to explore plasma acceleration, high-field physics, secondary sources of radiation, ultrafast processes, laboratory astrophysics, materials under extreme conditions, and applications extending into chemistry, biology, medicine, and materials science. This range of possible research made the facility interdisciplinary by design. It also meant that physics at ELI could not be separated from engineering, safety, optics, vacuum technology, control systems, computational modelling, and user support. The facility therefore became a place where scientific knowledge and organisational knowledge were inseparable. Czech science gained not only a laser centre but also practical experience in operating an international research infrastructure under European conditions.

The importance of ELI was further reinforced by the European Research Infrastructure Consortium model. The establishment of ELI ERIC placed ELI Beamlines within a formal European governance structure, turning the Czech facility into a pillar of a distributed European infrastructure rather than a purely national project (*ELI ERIC, n.d.*). This was institutionally significant because ERIC status changes the meaning of ownership and participation. A facility

may be located in one country, but its scientific community, evaluation mechanisms, and strategic development are European. For the Academy, this meant that national prestige had to be balanced with transnational responsibility. The Academy could claim an important role in the facility's development, yet the logic of operation required openness to users and partners beyond the Czech Republic. In this way, ELI became a concrete expression of the Academy's modern internationalisation.

The HiLASE Centre formed another important element of the Czech laser landscape. As a scientific research centre of the Institute of Physics, it focused on high average power pulsed lasers and on the development of laser technologies with potential applications in industry, space technologies, materials processing, and other advanced technological domains (*HiLASE Centre, n.d.*). Its role differed from that of ELI Beamlines, although the two centres belonged to the same broader ecosystem of advanced laser research. HiLASE was more visibly connected to application-oriented laser technologies, high-power diode-pumped solid-state lasers, surface processing, micromachining, laser shock peening, and cooperation with users beyond academic physics. In institutional terms, it showed how the Academy could connect fundamental physical competence with technological development without abandoning its scientific mission. It also illustrated how research infrastructures could become bridges between the Academy, industry, and European technological sovereignty.

The Prague Asterix Laser System, usually known as PALS, represented an earlier but still important infrastructure tradition. Established as a joint research laboratory of the Institute of Physics and the Institute of Plasma Physics in 1998, PALS provided a high-power laser facility for experiments in laser–matter interaction, laser plasma, laboratory astrophysics, fusion-related research, and plasma chemistry (*PALS Research Centre, n.d.*). Its history is important because it shows that the infrastructure turn did not begin only with the large European projects of the 2010s. The Czech Academy had already experimented with user-type laser facilities and international access before the full institutionalisation of ELI. PALS also created a bridge between optical physics and plasma physics, between older Czechoslovak expertise and newer European networks such as Laserlab-Europe. In this respect, it served as a transitional infrastructure, preparing scientific and organisational habits later required by larger projects.

Plasma physics and fusion research formed another major infrastructure domain. The Institute of Plasma Physics of the Czech Academy of Sciences became the main Czech academic centre for fusion research and maintained links with the European fusion programme through EUROfusion and other international frameworks (*Institute of Plasma Physics of the CAS, n.d.*; *EUROfusion, n.d.*). The operation of the COMPASS tokamak in Prague placed Czech researchers within a highly specialised European community concerned with magnetic confinement, plasma edge physics, diagnostics, and scenarios relevant to ITER and DEMO. The importance of COMPASS lay not only in the scientific results produced by the machine, but also in the training of people, the development of diagnostics, and the integration of Czech teams into European fusion planning. A tokamak is not simply an instrument; it is an institutional school. It teaches researchers how to think in terms of coordinated experiments, machine campaigns, shared databases, operational safety, and long-term technological goals.

The move towards COMPASS-U further deepened this infrastructural logic. The COMPASS-U project was conceived as a strategic upgrade designed to address key problems in

contemporary fusion research, including high-field operation, advanced plasma configurations, and issues relevant to European and ITER-related priorities (*Institute of Plasma Physics of the CAS, n.d.*). This shows a characteristic feature of modern infrastructure policy: smaller or medium-sized countries can contribute to global science not by duplicating the largest facilities, but by constructing specialised machines that answer well-defined problems within a larger research ecosystem. COMPASS-U was therefore not intended to compete with ITER or the largest European tokamaks. Its role was to provide a distinctive experimental capacity within a distributed structure of fusion research. For the Academy, such a project confirmed that institutional relevance could be achieved through specialisation, not only through size.

Fusion research also reveals the political dimension of scientific infrastructure. The promise of thermonuclear fusion links physics to energy security, climate policy, industrial capacity, and long-term public investment. Yet fusion remains a field in which the horizon of practical application is distant and uncertain. This creates a particular institutional challenge. Research must be justified not by immediate return, but by participation in a long civilisational project of energy transformation. The Academy's role here is to preserve the scientific and technical continuity necessary for such long projects. It provides expertise, trains researchers, operates specialised equipment, and participates in European networks that no private company or short-term grant scheme could maintain alone. In fusion, the Academy's public character becomes especially visible.

Nuclear physics infrastructures created another field in which the Academy combined national responsibility with international cooperation. The Nuclear Physics Institute of the Czech Academy of Sciences in Řež operated the CANAM infrastructure, which provided experimental facilities for accelerated ion beams, neutron research, nuclear analytical methods, and related applications (*Nuclear Physics Institute of the CAS, n.d.*). CANAM's open access mode made it part of the broader European movement towards shared research facilities. Its users could come from academic institutions, industry, and interdisciplinary fields requiring nuclear analytical expertise. This infrastructure linked basic nuclear physics with materials research, environmental studies, cultural heritage analysis, dosimetry, radiopharmaceutical research, and neutron methods. The Academy therefore maintained a type of expertise that was both highly specialised and socially relevant.

The CANAM infrastructure is historically significant because nuclear physics in the Czech lands had long been associated with state priorities, energy, and Cold War scientific modernity. After 1989, this legacy had to be reinterpreted. The Academy did not simply abandon nuclear expertise because it had once belonged to a politically charged technological field. Instead, it re-situated nuclear physics within open scientific collaboration, interdisciplinary services, and European standards of access and evaluation. This transformation is typical of the post-socialist Academy. It did not erase inherited capacities; it changed their institutional meaning. Facilities once embedded in a centrally planned scientific order became parts of a plural, internationally connected, publicly accountable research system.

Materials and nanotechnology infrastructures extended the Academy's physical sciences into another strategic domain. CzechNanoLab provided open access to advanced tools and expertise in nanoscience, nanotechnology, and materials research, with distributed sites including Prague and Brno and participation of Academy institutes and university partners (*CzechNanoLab, n.d.*). Its importance lies in the fact that nanoscience cannot be developed

through theory alone. It requires cleanrooms, lithography, deposition systems, electron microscopy, scanning probe methods, cryogenic measurements, and specialised technical knowledge. By participating in CzechNanoLab, Academy institutes helped to create a national platform through which researchers from different institutions could access expensive and delicate instrumentation. This strengthened the connection between physics, materials science, chemistry, electronics, and biomedical research.

The Materials Growth and Measurement Laboratory, or MGML, added a complementary dimension to this infrastructure landscape. It provided access to advanced equipment and expertise for the synthesis, characterisation, structural analysis, and measurement of materials, with a strong orientation towards condensed matter physics and materials science (*Materials Growth and Measurement Laboratory, n.d.*). MGML's cooperation between Charles University and the Institute of Physics of the Czech Academy of Sciences is especially revealing because it shows how the boundaries between Academy and university research became increasingly porous. The Academy supplied long-term research expertise and instrumentation culture, while the university environment supported teaching, doctoral training, and disciplinary continuity. Such shared infrastructures were not merely administrative partnerships. They embodied a practical division of labour within the national research system.

The connection between infrastructure and international collaboration was especially strong in particle physics. The Czech participation in CERN experiments depended on the CERN-CZ research infrastructure, coordinated through the Institute of Physics and involving several Czech institutions, including universities and the Nuclear Physics Institute (*CERN-CZ, n.d.*). The purpose of this infrastructure was to support Czech contributions to the development, construction, maintenance, operation, and data processing of CERN experiments. This is a very different model from classical laboratory ownership. Czech physicists do not "own" CERN, yet they participate in its experiments through detector work, electronics, software, computing, physics analysis, and long-term collaboration. The Academy's role was to secure a national institutional platform through which Czech teams could contribute credibly to one of the world's central sites of high-energy physics.

CERN-CZ also shows how infrastructure can exist partly outside national territory. In such cases, the national infrastructure is not a single building but a coordinated system of expertise, funding, equipment, computing, and institutional agreements. Czech detector components may be developed at home, installed abroad, and used by international collaborations. Data may be produced at CERN, processed through distributed computing, and analysed by teams in Prague, Řež, or university departments. This distributed character changes the meaning of scientific participation. A national research system must be able to maintain domestic competence while operating in a global experimental environment. The Academy's institutes became crucial because they provided continuity, technical reliability, and institutional memory across projects lasting decades.

Astroparticle physics followed a similar but distinct pattern. The Czech participation in the Cherenkov Telescope Array through CTA-CZ linked the Institute of Physics with Charles University and Palacký University in a European and international infrastructure for very-high-energy gamma-ray astronomy (*CTA-CZ, n.d.*; *Ministry of Education, Youth and Sports, 2024*). Czech researchers contributed notably to the preparation of telescope mirrors, optical systems, site evaluation, and related technological tasks. This is an important example of how national strengths in optics, precision engineering, and instrumentation could be translated

into global science. The study of cosmic gamma rays is a highly abstract field, concerned with extreme astrophysical sources and fundamental processes. Yet Czech participation depended on very concrete material competences: mirrors, coatings, alignment, optical quality, calibration, and data interpretation.

The Academy's involvement in astroparticle infrastructures also broadened the cultural meaning of physics. The same institutional world that studied solid surfaces, lasers, plasma, and nuclear reactions could also participate in the investigation of cosmic accelerators, black holes, supernova remnants, and high-energy phenomena beyond the Earth. This extension from matter in the laboratory to matter and radiation in the Universe shows the breadth of the Academy's physical sciences. It also shows that infrastructure is not only a technical device but a way of expanding the imagination of a research community. A telescope array, a laser facility, a tokamak, and an accelerator all enlarge the range of possible questions. They allow scientists to ask what could not be asked, or at least could not be answered, within smaller laboratory traditions.

International collaboration changed not only the scale of research but also the everyday culture of Czech physics. Researchers had to publish in international journals, participate in working groups, attend collaboration meetings, prepare joint proposals, respond to external evaluation, share data, follow common technical standards, and communicate across institutional and linguistic borders. Younger scientists were socialised into an environment where a Czech affiliation was compatible with a strongly international scientific identity. This differed sharply from the more enclosed conditions of the socialist period, even though some international contacts had existed earlier. After 1989, internationalisation became systemic rather than exceptional. It was built into the very operation of infrastructures, not added as a diplomatic supplement to national research.

The infrastructure regime also affected governance inside the Academy. Large facilities required project management, legal agreements, procurement procedures, user offices, safety structures, technical maintenance, strategic planning, and professional communication. This placed new demands on institutes traditionally organised around scientific departments and research groups. Directors and scientific councils had to deal not only with academic evaluation but also with infrastructure sustainability, investment cycles, user access, and international accountability. In this sense, the physical sciences contributed to the modernisation of Academy governance. They forced the institution to develop capacities that were administrative in form but scientific in purpose. Managing a large research infrastructure became part of doing science.

Funding was a central element of this change. Large infrastructures could not be sustained by ordinary institutional budgets alone. They required national investment, European structural funds, competitive projects, international membership fees, and long-term operational support. This created both opportunities and vulnerabilities. On the one hand, Czech physics gained access to resources that would have been unimaginable in a purely national laboratory system. On the other hand, dependence on large funding cycles exposed institutes to political decisions, budgetary negotiations, and shifting priorities in research policy. The Academy therefore had to learn how to defend the public value of expensive science. It had to explain why lasers, tokamaks, accelerators, detectors, and nanotechnology cleanrooms were not luxuries, but conditions for participation in advanced knowledge economies.

The relationship between infrastructure and autonomy was therefore complex. At first glance, dependence on large national and European funding programmes might seem to reduce institutional autonomy. Yet without such programmes, the Academy would be unable to sustain the scientific capacities necessary for modern physics. Autonomy in this context did not mean financial isolation. It meant the ability to participate in infrastructure governance, define scientific priorities within international frameworks, protect expert judgement, and maintain long-term competence despite political and economic changes. The Academy's autonomy was thus reconstructed through networks. It became less a matter of withdrawal from the state or Europe and more a matter of negotiating scientific authority within them.

Research infrastructures also strengthened the Academy's relations with universities. In physics, doctoral education and advanced training increasingly depended on access to facilities that no single faculty could easily maintain. Academy institutes offered laboratories, instruments, supervisors, technical staff, and participation in international collaborations. Universities offered students, curricula, degree frameworks, and broader disciplinary communities. Shared infrastructures such as CzechNanoLab and MGML made this interdependence concrete. The Academy's laboratories were no longer merely workplaces for professional researchers; they were training environments for future physicists, engineers, materials scientists, and data specialists. This educational role was indirect but essential. It helped to reproduce national scientific capacity at the level required by contemporary physics.

Infrastructure also created new forms of collaboration with industry. In some areas, especially lasers, materials, nanotechnologies, detector technologies, and nuclear analytical methods, industrial partners could use Academy expertise for testing, development, measurement, and innovation. This did not mean that the Academy became an industrial research office. Rather, it occupied a position between fundamental science and technological capability. It could support industrial innovation precisely because it possessed deep knowledge and instruments that were not designed for immediate commercial routine. This is an important distinction. The Academy's contribution to innovation was strongest when it remained rooted in serious scientific competence, not when it imitated short-term product development.

The international infrastructure orientation also helped Czech science overcome some of the disadvantages of national scale. The Czech Republic could not independently build the full range of global physics facilities. It could not duplicate CERN, ITER, the European Spallation Source, or all next-generation observatories. But it could host selected specialised facilities, participate in distributed infrastructures, contribute technical components, train researchers, and maintain recognised expert groups. The Academy's role was to make this strategy possible. It provided institutional continuity across political cycles and enabled Czech teams to remain visible in fields where scientific authority depends on long-term presence. This was a realistic and effective model for a medium-sized European country with strong scientific traditions but limited resources.

At the same time, infrastructure-based science introduced tensions into the Academy. Large facilities can concentrate resources, prestige, and administrative attention. Smaller research groups may fear marginalisation when policy favours visible infrastructures. The Academy therefore had to balance big science with investigator-driven research, long-term expertise with competitive funding, and national priorities with international obligations. This balance was not always easy. Yet the physical sciences show that large infrastructures and smaller research schools need not be enemies. In the best cases, infrastructures provide tools,

visibility, and training opportunities that strengthen smaller groups. Conversely, infrastructures remain scientifically alive only when they are used by creative researchers capable of asking original questions.

The Academy's research infrastructures also had a public dimension. Facilities such as ELI Beamlines, HiLASE, COMPASS-U, CANAM, CzechNanoLab, MGML, CERN-CZ, and CTA-CZ offered visible evidence that Czech science belonged to the front rank of European research. They served as symbols of national modernity after the post-socialist transition. Their buildings, instruments, and international collaborations became part of a broader public narrative about innovation, European integration, and scientific competence. This symbolic function should not be dismissed as superficial. Public research institutions need legitimacy. Large infrastructures helped show society that the Academy was not a relic of the Czechoslovak Academy of Sciences, but a transformed institution capable of operating in the most demanding areas of contemporary science.

The long-term effect of these infrastructures was to redefine the Academy's place in the Czech research and innovation system. It became not only a producer of publications but also an operator of platforms on which others could produce knowledge. This platform role is crucial. A research infrastructure multiplies scientific capacity beyond the staff of the institute that hosts it. It supports external users, doctoral students, international teams, industrial partners, and interdisciplinary projects. The Academy thus acted as a national custodian of scientific possibility. It maintained conditions under which future discoveries could occur, even when their exact direction could not be predicted in advance.

Thus, research infrastructures and international collaborations became one of the central mechanisms through which the Czech Academy of Sciences entered the contemporary European research order. In physics, this transformation was especially visible because the study of matter increasingly depended on lasers, tokamaks, accelerators, detectors, nanotechnology platforms, nuclear analytical facilities, and global observatories. The Academy's role was not simply to preserve inherited Czechoslovak scientific traditions, although it did that as well. Its deeper achievement was to convert those traditions into open, networked, internationally evaluated, and technologically demanding forms of research. Through ELI Beamlines, HiLASE, PALS, COMPASS-U, CANAM, CzechNanoLab, MGML, CERN-CZ, CTA-CZ, and related collaborations, the Academy helped ensure that Czech physics remained present where the most advanced questions of matter, energy, radiation, and the Universe were being asked.

3. The Academy's Role in Advanced Physical Research

The role of the Czech Academy of Sciences in advanced physical research cannot be reduced to the existence of several strong institutes or to the operation of expensive laboratories. Its deeper significance lies in the capacity to hold together a complex chain of scientific functions that are difficult for any other type of institution to sustain in full. The Academy preserves long-term expertise in fundamental physics; it operates infrastructures that require decades of continuity; it provides an institutional home for research fields whose practical value may be enormous but whose results cannot be scheduled according to short political or commercial cycles. It also gives Czech science access to the intellectual and experimental frontier of contemporary physics, where matter is studied through extreme light, high magnetic fields,

particle collisions, nuclear reactions, nanostructures, detectors, plasma, and cosmic radiation. In this sense, the Academy is not simply one participant in the national research system. It is one of the institutions that makes advanced research possible at the national level. Its role is especially visible in physics because modern physics depends on a rare combination of conceptual abstraction, technological precision, engineering competence, data capacity, international trust, and long-term public support (*Akademie věd České republiky, n.d.*; *Fyzikální ústav AV ČR, n.d.*).

This role has a historical depth. The Academy inherited parts of the Czechoslovak scientific system that had been formed under different political regimes, from the early post-war institutionalisation of science to the centralised structures of the Czechoslovak Academy of Sciences and then to the reformulated public research institutions of the Czech Republic. Physics was one of the domains in which this inheritance proved particularly important. Laboratories, technical workshops, scientific schools, instrument-building traditions, and international contacts could survive political discontinuities more easily than ideologically exposed fields, although they were by no means unaffected by politics. After 1989, the Academy's task was not merely to "continue" Czechoslovak physics, but to translate its accumulated capacities into a new environment of evaluation, European integration, grant competition, institutional autonomy, and public accountability. Advanced physical research therefore became one of the arenas in which the post-socialist Academy demonstrated that inherited expertise could be reoriented without being destroyed. The transformation of physics in the Academy was thus both a scientific process and an institutional act of historical conversion.

The Academy's first major role was to provide continuity where scientific time is longer than political time. Research in condensed matter physics, optics, plasma physics, nuclear physics, and particle physics often unfolds across decades. A scientific group may need many years to build a method, master an instrument, train students, join an international collaboration, or develop a specific line of interpretation. Such research cannot be rebuilt quickly if institutional memory is lost. The Academy's organisational form gave Czech physics a protective environment in which knowledge could be accumulated, revised, transmitted, and expanded. This did not mean isolation from evaluation or from external expectations. On the contrary, the modern Academy increasingly had to prove the quality of its research through international comparison. Yet it retained a distinctive ability to sustain long-term fields that would be vulnerable if judged only by immediate application or short project cycles.

The second major role of the Academy was to connect fundamental science with technological capacity without dissolving one into the other. Advanced physics often produces knowledge whose application is uncertain at the moment of discovery, but it also demands technologies that later become socially and economically important. Lasers, detectors, vacuum systems, cryogenics, accelerators, nanofabrication, optical coatings, plasma diagnostics, ion-beam methods, and numerical modelling are not merely tools for physicists. They form a reservoir of technical competence that can influence medicine, energy, electronics, materials engineering, cultural heritage research, environmental monitoring, security, and industrial innovation. The Academy's strength lay in preserving the autonomy of basic research while allowing such competences to circulate beyond narrow disciplinary boundaries. This balance was essential. If physics were reduced to technological service, its creative depth would decline; if it were isolated from public and technological needs, its institutional legitimacy

would become fragile. The Academy's role was to keep these two dimensions in productive tension.

This tension can be seen most clearly in the Institute of Physics of the Czech Academy of Sciences. As the largest and most visible centre of Academy physics, it concentrated several strategic fields: elementary particle physics, condensed matter and solid-state physics, optics, plasma physics, and laser physics (*Fyzikální ústav AV ČR, n.d.*). The importance of this profile lies not only in disciplinary breadth. It allowed the Institute to connect different scales of matter and different scientific cultures. A single institutional environment could include researchers working on subatomic particles, magnetic and electronic properties of solids, optical systems, high-power lasers, detector technologies, and astroparticle phenomena. Such breadth is institutionally rare because it requires not only scientific diversity but also administrative flexibility, technical infrastructure, and a shared commitment to international standards. In the Academy's history, the Institute of Physics therefore functioned as both a centre of specialisation and a mechanism of integration.

The Academy's role in advanced physical research also includes the maintenance of experimental cultures that are not easily visible in general accounts of science policy. Physics is often described through great discoveries, theoretical ideas, or large projects, but the daily life of advanced research depends on many less spectacular forms of competence. Instruments must be designed, calibrated, repaired, upgraded, and adapted to new questions. Experimental conditions must be stabilised and reproduced. Data must be cleaned, interpreted, archived, and compared with models. Technical staff, engineers, doctoral students, postdoctoral researchers, and senior scientists must cooperate across hierarchies of expertise. The Academy provides an institutional environment in which these practical cultures of precision can be sustained. This is especially important in a medium-sized country, where the loss of one specialised laboratory or technical team may mean the loss of a national capacity.

In condensed matter and materials research, this institutional function is especially important. The study of solids, surfaces, nanostructures, magnetic materials, crystals, semiconductors, and functional materials requires specialised instruments and accumulated interpretative experience. It also requires patience, because the path from a physical mechanism to a useful material may be indirect and non-linear. The Academy's institutes have been able to preserve this kind of research because their mission is not limited to teaching cycles or commercial product development. They can support long investigations into the structure and behaviour of matter, while still creating possibilities for innovation in electronics, photonics, energy materials, sensors, and nanotechnologies. The value of this role becomes clearer when one considers how many modern technological revolutions have emerged from research that was originally concerned with fundamental properties of matter. In this sense, the Academy's condensed matter research was not a passive continuation of older solid-state physics, but a living field in which scientific curiosity and technological potential remained closely connected.

Optics and laser physics reveal another aspect of the Academy's role: the ability to transform older national strengths into new international platforms. Czech scientific and technical culture had long been associated with precision instruments, glass, microscopy, optical design, and engineering craftsmanship. The Academy did not abandon these traditions in the post-socialist period; instead, it helped recast them in the language of photonics, laser

physics, nonlinear optics, ultrafast science, and high-power laser technology. Facilities such as ELI Beamlines and HiLASE show that this transformation could reach European significance (*ELI Beamlines, n.d.*; *ELI ERIC, n.d.*; *HiLASE Centre, n.d.*). The Academy's role here was not merely to participate in the global laser community, but to host facilities that could attract international users and position Czech science within frontier research. This transformed the cultural meaning of Czech optics: it became not only a heritage of skilled instrumentation, but also a contemporary instrument of scientific visibility.

ELI Beamlines is particularly important because it shows how the Academy moved from national expertise to European-scale responsibility. A high-intensity laser facility of this kind changes the institutional conditions of science. It requires not only excellent physicists, but also project managers, safety specialists, engineers, user support systems, international governance, and a reliable framework for access by external researchers. The Academy's participation in ELI therefore demonstrated that it could operate within the culture of European big science. It also made Czech physics visible in fields such as laser-plasma interaction, ultrafast processes, secondary radiation sources, materials under extreme conditions, and laboratory astrophysics. Such visibility matters historically because it alters the relationship between a national research system and the international scientific centre. Czech physics was no longer only sending researchers to large facilities abroad; it was also helping to provide infrastructure for others. This was a substantial shift in scientific status.

HiLASE expressed a complementary role. While ELI Beamlines was associated with extreme light and user-oriented frontier experiments, HiLASE focused on high average power pulsed laser technologies with strong relevance for research and advanced applications (*HiLASE Centre, n.d.*). Its significance for the Academy lies in the way it connected scientific depth with technological development. High average power lasers are not merely scientific curiosities; they have potential uses in materials processing, surface treatment, micromachining, space technologies, industrial metrology, and other high-technology domains. Yet the competence needed to develop such systems is rooted in demanding basic physics and engineering. The Academy's role was to provide the environment where such competence could mature without being reduced to routine industrial service. HiLASE therefore illustrates the Academy's ability to occupy a middle space between fundamental optical physics and innovation policy.

Plasma physics and fusion research demonstrate the Academy's role in even longer historical horizons. The Institute of Plasma Physics has placed Czech science within one of the most ambitious international research projects of the modern age: the search for controlled thermonuclear fusion. Fusion research requires an unusual kind of institutional patience. Its promise is enormous, but its practical realisation depends on solving problems that involve plasma confinement, turbulence, edge physics, materials under extreme loads, diagnostics, heating, magnetic control, and reactor-relevant engineering. No short-term institution can carry such a field alone. The Academy's role has been to sustain national expertise in this area, to operate specialised devices, to train researchers, and to connect Czech teams with the European fusion programme (*Institute of Plasma Physics of the CAS, n.d.*; *EUROfusion, n.d.*). In this field, the Academy is not merely producing knowledge; it is preserving the possibility that Czech science will remain part of a future energy transformation.

The COMPASS and COMPASS-U projects illustrate this responsibility. COMPASS allowed Czech researchers to participate actively in tokamak research relevant to European fusion priorities, while COMPASS-U was conceived as a high-field facility with plasma geometries and

operational flexibility relevant to ITER and DEMO challenges (*Institute of Plasma Physics of the CAS, n.d.*). The point is not that the Czech Republic would build a fusion reactor independently. Rather, the Academy created and maintained a specialised research niche within a much larger European ecosystem. This is exactly how a medium-sized scientific country can participate meaningfully in global advanced research: by contributing distinctive expertise, well-defined experimental capacity, and reliable institutional continuity. The Academy's role is therefore strategic, not merely supportive. It gives Czech science a voice in a field where future technological and energy systems may be shaped.

Nuclear physics reveals a similar but historically distinct role. The Nuclear Physics Institute in Řež carries the legacy of Czechoslovak nuclear research while operating in a transformed democratic and European research environment. Its work spans theoretical nuclear and particle physics, heavy-ion physics, nuclear reactions, neutron and ion methods, accelerator operation, radiation dosimetry, radiopharmaceuticals, and related applications (*Nuclear Physics Institute of the CAS, n.d.*). This diversity is important because nuclear physics is not one field in a narrow sense. It touches fundamental questions about nuclear matter, astrophysical processes, weak interactions, and particle properties, but it also supports medicine, radiation protection, materials analysis, environmental studies, archaeology, and public safety. The Academy's role is to keep these dimensions connected under conditions of scientific responsibility. In a society where nuclear technologies carry both promise and anxiety, independent and competent public research expertise is indispensable.

The Centre of Accelerators and Nuclear Analytical Methods, or CANAM, shows how this expertise becomes a national resource. By grouping major experimental facilities and providing open access for research with accelerated ion and neutron beams, CANAM extends the Institute's capacities beyond its own internal staff (*Nuclear Physics Institute of the CAS, n.d.*). This is an important institutional model. The Academy does not only conduct research; it creates conditions under which other researchers, including those from universities and interdisciplinary fields, can conduct research. Through nuclear analytical methods, accelerator beams, neutron laboratories, and dosimetry expertise, the Academy provides forms of knowledge that may be needed by physicists, chemists, materials scientists, archaeologists, medical researchers, and environmental specialists. The role of advanced physical research is therefore not confined to physics itself. It becomes part of the shared infrastructure of national knowledge.

High-energy and astroparticle physics further expand the Academy's function as an interface between national science and global collaborations. Czech researchers cannot reproduce CERN, the Pierre Auger Observatory, or the Cherenkov Telescope Array within national borders. Yet through Academy institutes, they can participate in detector development, optics, data analysis, computing, instrumentation, and interpretation. Such participation requires long-term institutional commitment because international collaborations often last for decades and depend on accumulated credibility. The Academy's contribution is therefore not measured only by the number of domestic facilities. It is also measured by the ability to keep Czech teams present in international experiments where the fundamental structure of matter and the high-energy Universe are investigated. This form of participation is a modern expression of scientific sovereignty: the country does not own the global infrastructure, but it possesses the expertise necessary to help create and use it.

The Academy's role in advanced physical research is also educational, even though the Academy is not a university in the classical sense. Its institutes supervise doctoral students, host young researchers, provide access to laboratories, and create research environments that universities alone could not easily reproduce. Advanced physics cannot be learned fully from lectures or textbooks. It must be learned through participation in experiments, modelling, instrument operation, data analysis, international meetings, and the tacit discipline of laboratory work. The Academy therefore acts as an extended training system for the Czech research community. It helps form future physicists, engineers, data scientists, materials researchers, and technical specialists. This role is vital because the continuity of advanced science depends on human transmission as much as on buildings and machines.

The relationship with universities is therefore one of interdependence rather than rivalry. Universities provide degree structures, broad teaching, student recruitment, and disciplinary education. The Academy provides concentrated research environments, large instruments, specialised teams, and access to international collaborations. In fields such as condensed matter physics, laser science, plasma physics, nuclear physics, and particle physics, neither side can fully replace the other. The strongest model is cooperation: joint supervision, shared laboratories, mobility of researchers, common infrastructure use, and participation in national and European projects. This cooperation helps to integrate the Czech research system and prevents the separation of teaching from frontier research. It also reflects a wider European pattern in which academies, universities, and research infrastructures form interconnected rather than isolated parts of scientific life.

The Academy's public research mission is also expressed through the Strategy AV21 framework. Strategy AV21 emphasises research in the public interest and the formulation of coordinated programmes responding to contemporary social challenges (*Strategy AV21, n.d.*). For the physical sciences, this framework is significant because it situates advanced physics within broader public concerns without reducing it to immediate utility. Programmes connected with light, energy, diagnostic methods, materials, nuclear systems, environmental challenges, and technological futures can draw on the expertise of physicists while also involving chemists, biologists, engineers, medical researchers, and social scientists. This approach reflects a mature understanding of public value. Physics serves society not only when it produces a ready-made technology, but also when it creates knowledge, instruments, methods, and expert communities capable of addressing future problems.

At the same time, the Academy must protect the internal logic of basic research. The history of physics shows that many of the most transformative applications emerged from investigations that were not initially application-driven. Quantum mechanics, nuclear magnetic resonance, lasers, semiconductors, particle detectors, and synchrotron methods all demonstrate the unpredictability of scientific utility. If the Academy were forced to justify advanced physics only through short-term usefulness, it would weaken the very source of future innovation. Its institutional role is therefore partly defensive: it defends the legitimacy of curiosity-driven research in a public environment that often demands immediate returns. This defence is not a retreat from society. It is a responsible reminder that advanced societies need institutions capable of thinking beyond the next budget cycle.

Evaluation and accountability changed this role after the post-socialist reforms. The Academy could no longer rely on inherited prestige or administrative protection. Its institutes had to demonstrate international quality through publication performance, external assessment,

competitive projects, and participation in recognised networks. For physical research, this was both a challenge and an opportunity. The standards of physics are strongly international, and successful groups could show their value through journals, collaborations, citations, invited talks, infrastructure roles, patents, instruments, and European projects. However, evaluation also risked simplifying the diversity of scientific contribution. The Academy had to argue that high-quality science includes not only papers but also the maintenance of infrastructure, training, technical development, open access facilities, and expert services. Advanced physical research thus helped broaden the meaning of research performance.

Internationalisation is central to this story. The Academy's role in physics increasingly depends on its ability to act across borders. Participation in ELI ERIC, EUROfusion, CERN-related activities, CTAO, European laser networks, nuclear infrastructures, and materials platforms situates Czech physics within international systems of trust and responsibility (*ELI ERIC, n.d.*; *EUROfusion, n.d.*; *Ministry of Education, Youth and Sports, 2024*). This is not merely a matter of prestige. It changes how research is planned, funded, evaluated, and performed. International collaboration forces institutes to meet common standards, share data, coordinate schedules, manage intellectual property, and contribute to long-term strategic agendas. The Academy thereby becomes a diplomatic as well as scientific actor, although its diplomacy is conducted through instruments, expertise, and reliability rather than political language.

This international role also reshapes national identity. Czech physics is not less national because it is international. On the contrary, its international presence gives national science substance. A small or medium-sized country demonstrates scientific maturity not by isolating its researchers, but by enabling them to contribute to global knowledge on equal terms. The Academy's role is to ensure that Czech participation is not episodic or dependent only on individual careers abroad. It provides institutional continuity, laboratories, administrative support, and strategic direction. Through this support, Czech scientists can enter global collaborations as members of a national scientific community with its own capacities and traditions. The result is a form of national scientific identity that is open, networked, and internationally validated.

The Academy also has a role in preserving technical professions that are often undervalued in public discussions of science. Advanced physical research depends on engineers, technicians, instrument specialists, software developers, safety officers, workshop staff, vacuum experts, electronics specialists, mechanical designers, and data infrastructure professionals. These people do not always appear as first authors of major scientific papers, but without them large parts of physics would be impossible. The Academy's institute-based structure can provide more stable careers for such expertise than short-term project environments alone. This is not a secondary issue. The continuity of advanced research often depends less on brilliant isolated individuals than on the existence of teams in which scientific and technical knowledge are intertwined. The Academy's role is therefore also to maintain the social ecology of research.

Advanced physical research has a strong regional dimension as well. Facilities in Prague, Dolní Břežany, Řež, Brno, and other locations create scientific geographies that link the Academy to cities, universities, innovation zones, and local economies. Dolní Břežany, for example, became associated with high-power laser research through ELI and HiLASE, while Řež remained a key site for nuclear physics and accelerator-based research. These places are not merely addresses. They are nodes where infrastructure, labour markets, education,

international visitors, and technological development intersect. The Academy thus contributes to the spatial organisation of Czech science. It helps create research environments whose influence extends beyond individual institute walls.

The Academy's physical sciences also contribute to public understanding of science. Physics often deals with phenomena that are difficult for the general public to imagine: quantum states, plasma confinement, cosmic particles, nuclear reactions, ultrafast laser pulses, nanostructures, and elementary particles. By communicating these fields, Academy institutes help society understand why public investment in science matters. Science communication in this context is not only popularisation; it is part of democratic accountability. Citizens are asked to support research whose results may be long-term, abstract, or technically complex. The Academy must therefore explain not only what it does but why it matters. In advanced physics, this communicative role is particularly important because the distance between everyday experience and scientific practice can be very large.

The Academy's role in advanced physical research also has an ethical dimension. Powerful physical knowledge may be connected to energy systems, radiation, surveillance technologies, military possibilities, industrial transformation, environmental risks, and health applications. The Academy's public character places responsibilities on its institutes to maintain research integrity, transparency, safety, and public trust. This is especially relevant in nuclear physics, high-power lasers, plasma technologies, and large-scale infrastructures. Ethical responsibility here does not mean avoiding difficult science. It means conducting it within frameworks of safety, openness, peer review, expert accountability, and public benefit. The Academy's institutional culture must therefore combine scientific ambition with civic responsibility.

The institutional role of the Academy becomes clearer when compared with other actors in the research system. Universities are indispensable for education and broad disciplinary reproduction. Private companies are important for commercialisation and technological deployment. Ministries and agencies shape policy and funding. International organisations create frameworks for cooperation. The Academy, however, occupies a distinct position: it is a non-university public research institution with a long-term mandate across fundamental, strategic, and interdisciplinary science. In advanced physics, this position is especially valuable because the field requires continuity, autonomy, infrastructure, and expertise that cannot be supplied by market demand alone. The Academy's role is therefore not a duplication of university or industrial research, but a necessary institutional complement to both.

The political history of the Czech lands gives this role additional weight. The Academy and its predecessors operated through periods of national revival, imperial structures, democratic independence, Nazi occupation, state socialism, normalisation, revolution, and post-socialist reform. In each period, science was connected to questions of sovereignty, legitimacy, modernity, and European belonging. Advanced physical research after 1989 became one of the clearest signs that the Czech Republic could participate in the highest levels of international knowledge production. The Academy helped make this participation institutionally durable. Its laboratories and collaborations showed that Czech science was not merely recovering from the past, but actively shaping its future. In this sense, physics became part of the broader historical narrative of democratic scientific reintegration.

Yet this role is not without tension. Advanced physical research is expensive, and its social benefits are not always immediately visible. Large infrastructures can attract criticism if they

are perceived as elite projects disconnected from public needs. Competitive funding can create pressure on researchers and distort long-term planning. International collaboration can sometimes make national priorities appear secondary. The Academy must constantly navigate these tensions. Its legitimacy depends on showing that advanced physics is not a luxury but a foundation of intellectual, technological, and civic capacity. This requires careful governance, transparent evaluation, open communication, and continued attention to the balance between excellence and public value.

The Academy's contribution to advanced physical research is therefore best understood as a layered institutional function. It preserves historical continuity, but it also reforms inherited structures. It supports basic science, but it also enables innovation. It operates national laboratories, but it also participates in European and global infrastructures. It trains young researchers, but it also maintains expert technical teams. It serves the state and society, but it must retain enough autonomy to pursue questions whose importance may not yet be publicly obvious. These layers make the Academy more than an administrative umbrella for institutes. They make it an institutional form through which a national scientific community can remain present in the most demanding domains of contemporary knowledge.

Thus, the Academy's role in advanced physical research is one of the central expressions of its modern identity. Through the Institute of Physics, the Institute of Plasma Physics, the Nuclear Physics Institute, and related institutes in photonics, materials, instrumentation, mechanics, thermomechanics, astronomy, and information sciences, it sustains a national capacity to study matter, energy, radiation, and the Universe at the highest levels of complexity. It links Czechoslovak traditions with European infrastructures, fundamental curiosity with technological competence, national responsibility with international collaboration, and scientific autonomy with public accountability. This role cannot be captured by a simple list of discoveries or laboratories. It lies in the Academy's ability to create the institutional conditions under which advanced physical research can continue, adapt, and matter for society. In that sense, Czech physics within the Academy is not only a scientific field; it is a historical measure of the country's capacity to belong to the most demanding forms of modern European knowledge.

Chemistry and Materials Science

1. Continuities from Czechoslovak Chemical Schools

Chemistry within the Czech Academy of Sciences developed as one of the clearest examples of institutional continuity between the Czechoslovak Academy of Sciences and the post-1993 Czech Academy. Unlike some fields in the humanities and social sciences, where political regime changes directly reshaped research agendas, language, personnel, and legitimacy, chemistry possessed a different kind of historical resilience. Its objects of study were not free from politics, for laboratories, appointments, industrial priorities, travel, and international exchange were all conditioned by the political order. Yet the intellectual core of chemical research could maintain a significant continuity through changing regimes because it was

anchored in methods, instruments, schools, substances, and experimental practices. Organic synthesis, electrochemistry, macromolecular chemistry, chemical engineering, analytical chemistry, physical chemistry, catalysis, and materials research formed a set of traditions that survived institutional ruptures because they were transmitted through laboratories and research groups rather than only through formal statutes. The Czech Academy inherited these traditions not as static monuments but as living scientific cultures. Their continuity was therefore not passive preservation, but the repeated adaptation of Czechoslovak chemical schools to new political, institutional, and international conditions (*Akademie věd České republiky, n.d.*; *Institute of Organic Chemistry and Biochemistry, n.d.*).

The importance of chemistry in the Academy also reflected the wider social and economic history of the Czech lands. Bohemia and Moravia had long possessed strong traditions of technical education, chemical industry, glassmaking, pharmaceuticals, sugar production, brewing, petrochemistry, and later polymer and materials technologies. Chemistry therefore occupied a special position between academic science and industrial civilisation. It was intellectually close to physics and biology, but institutionally close to technology, medicine, agriculture, and production. This position made chemical research attractive to the state, to industry, and to scientific elites. It also gave chemists a particular kind of authority: they could speak both the language of fundamental transformations of matter and the language of practical usefulness. In the Academy, this dual position became one of the foundations of its strength in the life and chemical sciences.

The Czechoslovak Academy of Sciences, founded in 1952, provided chemistry with a centralised institutional framework at a moment when the socialist state sought to reorganise research according to the model of academies, institutes, and planned scientific priorities. The creation of Academy chemical institutes did not mean that Czech chemistry began in the 1950s. On the contrary, the Academy absorbed older university, industrial, and technical traditions and reorganised them into research institutes with long-term programmes. The significance of this process lies in the combination of rupture and continuity. The Academy was politically new and administratively centralised, but the scientific personnel, laboratory habits, and disciplinary cultures often came from pre-war and wartime experiences, technical universities, industrial laboratories, and earlier research schools. The socialist state created the institutional shell, but much of the scientific substance came from deeper Czech and Czechoslovak traditions.

The experience of the Second World War played an unexpected role in this continuity. After the closure of Czech universities by the Nazi regime in 1939, many teachers, students, and researchers were forced to seek work outside ordinary academic structures. Some moved into industrial laboratories or other technical environments, where they developed habits of practical problem-solving, experimental discipline, and cooperation with production. After the war, these experiences did not simply disappear. They influenced the way post-war Czech chemistry approached synthesis, instrumentation, technology, and institutional organisation. The later Academy institutes were therefore shaped not only by socialist planning but also by the memory of forced displacement from universities and by the laboratory cultures formed under emergency conditions. This made Czechoslovak chemistry less purely academic in the narrow sense and more attentive to the connection between research and material practice (*Institute of Organic Chemistry and Biochemistry, n.d.*; *Franc, 2024*).

The Institute of Organic Chemistry and Biochemistry became the most emblematic example of this continuity. Its official history traces its origins to a group of chemistry enthusiasts formed after the war at the Czech Technical University under the leadership of František Šorm, who played a decisive role in the founding of the institute. The institute was formally established in 1953 as the Institute of Organic Chemistry, later renamed the Institute of Organic Chemistry and Biochemistry of the Czechoslovak Academy of Sciences, and after 1993 became part of the Czech Academy of Sciences (*Institute of Organic Chemistry and Biochemistry, n.d.*). This institutional genealogy is important because it shows the transformation of a post-war chemical group into one of the central scientific institutes of the Academy. It also shows how the Academy was built through personalities capable of combining laboratory authority, organisational ambition, and political navigation. In the case of Šorm, these roles were particularly intertwined.

František Šorm embodied one of the central paradoxes of Czechoslovak chemical science. He was a major organic chemist, a powerful institution-builder, and a central figure in the early Czechoslovak Academy. His scientific work in natural products, biologically active compounds, and organic synthesis helped establish a strong school of chemical research. At the same time, he occupied high positions within the Academy's leadership, including the presidency of the Czechoslovak Academy of Sciences in the 1960s, which placed him within the political structures of socialist science. This dual position should not be simplified either into scientific heroism or into institutional compromise. It reveals the actual complexity of academic elites under state socialism. A scientific school could be strengthened through access to institutional power, while institutional power itself required negotiation with the political order.

The organic chemistry school associated with IOCB was significant because it developed at the boundary of synthesis, natural products chemistry, biochemistry, and later biomedical research. Organic synthesis in this tradition was not merely the production of molecules; it was a way of organising scientific imagination around structure, function, biological activity, and possible application. The institute's later strength in medicinal chemistry and molecular biology cannot be separated from this older culture of exact synthetic work. Chemical structures were treated as intellectually meaningful objects, but also as possible agents in biological systems. This gave the school a natural bridge to biochemistry, pharmacology, virology, and drug development. The Academy's institutional environment made it possible to cultivate this bridge over long periods, even when political and economic conditions changed.

The continuity of IOCB also demonstrates the importance of institute identity. A strong scientific institute is not only a workplace; it is a memory-bearing institution. It preserves styles of training, standards of publication, tacit techniques, expectations of originality, and stories about predecessors. The post-1993 Czech Academy did not create IOCB from nothing. It inherited a scientific culture that had already passed through wartime disruption, Stalinist centralisation, the reform atmosphere of the 1960s, normalisation, and the democratic transformation after 1989. Each period changed the institute, but none erased the importance of its chemical school. This continuity helps explain why IOCB became one of the most internationally visible institutes of the modern Academy. Its success rested on the accumulation of scientific capital across regimes rather than on the sudden invention of excellence after 1989.

Another central chemical school was electrochemistry and polarography, associated above all with Jaroslav Heyrovský. Heyrovský's discovery and development of polarography gave Czech and Czechoslovak chemistry one of its most internationally recognised achievements. His 1959 Nobel Prize in Chemistry for polarography represented not only an individual scientific honour but also a symbolic confirmation that Czech chemistry could contribute to the universal language of modern science (*Nobel Prize, n.d.*; *J. Heyrovský Institute of Physical Chemistry, n.d.*). Polarography was important because it combined physical chemistry, analytical chemistry, instrumentation, and methodology. It was a scientific technique, but also a school of thinking about electrochemical processes, measurement, and the relation between theory and application. Its institutionalisation within the Czechoslovak Academy gave it continuity beyond the lifetime of one discovery.

The Institute of Polarography was founded in 1950 under Heyrovský's directorship and became part of the newly constituted Czechoslovak Academy two years later. Its research focused on the theory of polarography, physico-chemical processes at mercury electrodes, methodology, instrumentation, and analytical applications (*J. Heyrovský Institute of Physical Chemistry, n.d.*). This institutional path is historically revealing. The institute preceded the full formation of the Academy but was then absorbed into it, showing how post-war scientific initiatives were reorganised within the new Academy system. The polarographic school therefore combined pre-Academy initiative, Academy institutionalisation, and international recognition. It became one of the most important sources of prestige for Czechoslovak chemical science.

The later J. Heyrovský Institute of Physical Chemistry was created in 1972 by merging the Institute of Polarography with the Institute of Physical Chemistry, both of which belonged to the Czechoslovak Academy of Sciences (*J. Heyrovský Institute of Physical Chemistry, n.d.*). This merger was more than an administrative event. It brought together electrochemistry, physical chemistry, theoretical chemistry, molecular spectroscopy, catalysis, adsorption, mass spectrometry, thermodynamics, kinetics, polymer science, organometallic chemistry, and other fields. The new institute became a broad centre of physical chemistry rather than only a memorial to polarography. Its history also carried the shock of the 1968 Warsaw Pact invasion, after which many scientists, including leading figures, emigrated to the West. The survival and later reform of the institute therefore illustrate how a scientific school could be wounded by political history and still retain enough intellectual continuity to renew itself.

Rudolf Brdička and later Rudolf Zahradník represented other layers of this physical-chemical continuity. Brdička was associated with the Institute of Physical Chemistry and with electrochemical and biochemical approaches that helped broaden the field beyond classical polarography. Zahradník, a theoretical and quantum chemist, became one of the founders of Czech and Central European quantum chemistry and later the first president of the Czech Academy of Sciences after the dissolution of Czechoslovakia (*J. Heyrovský Institute of Physical Chemistry, n.d.*; *Schwarz & Friedrich, 2021*). This trajectory is historically important because it links chemical science to the highest level of institutional leadership. The presidency of a chemist in the formative years of the Czech Academy symbolised the authority of the natural sciences within the post-socialist reconstruction of the institution. It also showed that chemical schools were not only laboratory traditions but sources of academic statesmanship.

The macromolecular school associated with Otto Wichterle formed another major line of continuity. The Institute of Macromolecular Chemistry was founded in 1959 by Wichterle, who also served as its first director and is internationally known for the invention of the soft contact

lens technology based on polymer materials (*Institute of Macromolecular Chemistry, 2019*). This school connected organic chemistry, polymer science, materials research, medical applications, and technological innovation. Wichterle's career demonstrates the unusual capacity of chemistry to move from molecular design to everyday human use. The soft contact lens became one of the most famous Czech scientific-technological achievements because it changed the lives of millions of people while remaining rooted in serious polymer chemistry. The Academy's history of chemistry cannot therefore be written only as a history of laboratories; it must include the transformation of chemical knowledge into social artefacts.

Wichterle's case also reveals the tension between scientific creativity and political constraint. He was an outstanding chemist and inventor, but his work unfolded under a regime that could both support scientific infrastructure and restrict independent personalities. The story of soft contact lenses is often remembered as a triumph of inventive persistence, especially because some of the decisive experimental steps were carried out outside the ideal conditions of official institutional planning. This should not be reduced to a romantic anecdote. It shows a structural feature of socialist science: institutional resources could be substantial, but creativity often had to move around bureaucratic rigidity and political mistrust. The macromolecular school survived because it was rooted not only in official plans but in personal ingenuity, experimental skill, and a community capable of recognising the importance of materials before their full application was obvious.

The Institute of Macromolecular Chemistry gave polymer science a stable Academy home. This mattered because macromolecular chemistry requires long-term integration of synthesis, physical characterisation, theory, processing, and application. Polymers are neither simple small molecules nor classical bulk materials; they require their own conceptual language of chains, networks, morphology, elasticity, swelling, biocompatibility, degradation, and phase behaviour. The institute's existence allowed the Academy to cultivate this language across generations. It also linked Czech chemistry to international developments in polymer science, materials chemistry, and biomedical materials. The continuity from Wichterle to later polymer research therefore expresses a broader Academy pattern: the transformation of a charismatic founder's school into an enduring institutional field.

Chemical engineering and process chemistry formed a different but equally important Czechoslovak school. The Institute of Chemical Process Fundamentals was formally established in the Czechoslovak Academy of Sciences in 1960 from two existing teams with older traditions: the Department of Chemical Technology headed by Vladimír Bažant and the Department of Chemical Engineering headed by George Standart (*Institute of Chemical Process Fundamentals, n.d.*). Bažant worked on organosilicon compounds and heterogeneous catalysis, while Standart developed research on distillation and extraction processes. Later, a group dealing with thermodynamics and phase equilibria under Eduard Hála joined the institute. This genealogy shows that the institute was founded not by abstract administrative division but by the convergence of technological chemistry, chemical engineering, catalysis, separation science, and physical chemistry. It represented the Academy's attempt to give fundamental depth to chemical processes relevant to industry and modern technology.

This chemical engineering tradition is important for understanding the Academy's place between science and production. Under socialism, chemical industry was treated as a strategic sector, and chemical technology had clear economic significance. Yet the best Academy research in this field was not simply factory troubleshooting. It sought theoretical and

experimental foundations for processes such as catalysis, thermodynamics, phase equilibria, separations, reaction engineering, and later environmental and energy-related processes. This gave the field a distinctive identity: it was close to industrial need but not reducible to it. The Academy's role was to make chemical technology intellectually deeper, more systematic, and more internationally comparable. In the post-socialist period, this tradition could be redirected towards environmental engineering, advanced materials, energy conversion, and sustainable process science.

Analytical chemistry developed another continuity, especially in Brno. The history of the Institute of Analytical Chemistry began in 1956, when a Laboratory for Gas Analysis was established by transferring a small research group from the Institute for Petroleum Research in Brno to the Czechoslovak Academy of Sciences; the initiative was made possible largely through the foresight of František Šorm, then Scientific Secretary of the Academy (*Institute of Analytical Chemistry, n.d.*). This origin is revealing because it again shows the movement from applied or industrially connected research into the Academy framework. Gas analysis, chromatography, separation methods, trace-element analysis, and later bioanalytical and environmental methods all required high precision and strong instrumentation. Analytical chemistry became a discipline of visibility: it made hidden substances, traces, contaminants, metabolites, and molecular signals measurable. In that sense, it contributed not only to chemistry but to medicine, biology, environmental protection, and cultural heritage.

The analytical school also illustrates how scientific continuity may be built around methods rather than around substances. Organic chemistry often follows classes of compounds; polymer chemistry follows macromolecular systems; physical chemistry follows processes and theories; analytical chemistry follows ways of detecting, separating, quantifying, and interpreting. This methodological identity gave the field adaptability. As biological sciences expanded into genomics, proteomics, medicine, and environmental research, analytical chemistry could move into new areas without losing its core. The Institute of Analytical Chemistry later emphasised research and development of analytical methods linked to biological sciences, human health, environmental protection, and education (*Institute of Analytical Chemistry, n.d.*). The continuity from gas analysis to modern analytical chemistry therefore shows the transformation of a relatively specialised post-war laboratory culture into a broadly enabling scientific field.

Inorganic chemistry and catalysis formed another layer of the Academy's chemical landscape, even when its institutional history is less commonly narrated through one internationally famous founder. Inorganic chemistry connects coordination compounds, solid-state materials, photochemistry, zeolites, organometallic systems, catalysis, nanomaterials, and environmental chemistry. Within the Academy's Section of Chemical Sciences, the Institute of Inorganic Chemistry belongs alongside the institutes of analytical chemistry, physical chemistry, chemical process fundamentals, macromolecular chemistry, and organic chemistry and biochemistry (*Akademie věd České republiky, n.d.*). This placement is important because inorganic chemistry serves as a bridge between molecular design, materials research, catalysis, and environmental applications. Its continuity from Czechoslovak chemical schools lies not only in named personalities but in a persistent competence in compounds, structures, reactivity, and materials relevant to modern chemical science.

The structure of the Academy's chemical section itself reveals the inherited plurality of Czechoslovak chemistry. The contemporary Czech Academy lists six institutes in the Section

of Chemical Sciences: the Institute of Analytical Chemistry, the Institute of Inorganic Chemistry, the J. Heyrovský Institute of Physical Chemistry, the Institute of Chemical Process Fundamentals, the Institute of Macromolecular Chemistry, and the Institute of Organic Chemistry and Biochemistry (*Akademie věd České republiky, n.d.*). This is not an arbitrary administrative arrangement. It represents the sedimentation of several major schools: analytical methods, inorganic and materials chemistry, electrochemistry and physical chemistry, chemical engineering and process fundamentals, polymer science, and organic-biochemical synthesis. The Academy therefore preserved the institutional memory of Czechoslovak chemical science by maintaining a differentiated ecology of institutes. This ecology allowed specialisation without fragmentation because the fields remained intellectually connected through materials, molecular structure, reaction mechanisms, instrumentation, and applications.

The political history of these schools was uneven. Some fields benefited from socialist state interest in chemical industry, pharmaceuticals, materials, and technological modernisation. Others suffered from ideological suspicion towards individual scientists, limits on international exchange, bureaucratic interference, shortages of equipment, and the political consequences of 1968 and normalisation. The J. Heyrovský Institute's own historical account notes the emigration of many members after the Warsaw Pact invasion and the extensive reforms after 1989, including greater autonomy, restructuring, a grant-based funding system, renewed international cooperation, and modernisation of experimental and computer facilities (*J. Heyrovský Institute of Physical Chemistry, n.d.*). This pattern was not unique to one institute. It reflected the broader experience of Academy science after the fall of the communist regime. Continuity did not mean that nothing changed; it meant that enough scientific capital survived to make reform meaningful.

The post-1989 transformation was therefore a decisive test for Czechoslovak chemical schools. The institutes had to adapt to international publication standards, competitive grants, external evaluation, new leadership cultures, legal transformation, and closer cooperation with universities and foreign partners. The dissolution of Czechoslovakia in 1993 created the Czech Academy of Sciences, but the chemical institutes did not begin anew. They carried forward the accumulated traditions of ČSAV while changing their institutional identity, funding environment, and scientific orientation. In this sense, the Czech Academy's chemistry was post-Czechoslovak but not post-historical. It remained deeply marked by Czechoslovak scientific schools, even as it entered the European research area and increasingly worked according to international standards.

The continuity of chemical schools also depended on people who acted as carriers of institutional memory. Professors, senior researchers, laboratory heads, technicians, instrument specialists, and doctoral supervisors transmitted practices that were rarely recorded fully in official documents. They taught younger researchers how to purify compounds, interpret spectra, run chromatographic systems, maintain electrodes, design polymerisation experiments, build apparatus, analyse reaction mechanisms, and write articles for international journals. This tacit continuity was as important as formal institutional succession. A scientific school lives when its methods are reproduced by new people who also learn how to change them. The Academy's institutes provided the social spaces where this transmission could occur across generations.

At the same time, the Academy's chemical schools were not closed dynasties. Their survival required openness to international science. Czech organic chemists, electrochemists, polymer scientists, process chemists, analytical chemists, and physical chemists had to participate in international journals, conferences, collaborations, and later European projects. Internationalisation after 1989 did not erase national traditions; it tested them. Schools that had been strong internally had to prove themselves externally. This process could be difficult, but it also gave the inherited traditions new vitality. The most successful institutes were those that converted Czechoslovak continuity into international credibility rather than treating continuity as sufficient in itself.

The relationship between Academy chemistry and universities was also central to continuity. Many of the chemical schools had roots in the Czech Technical University, the University of Chemistry and Technology in Prague, Charles University, Masaryk University, and other educational institutions. Academy institutes did not replace universities; they extended the research capacity of the national system. They offered laboratories, specialised instrumentation, long-term research programmes, and doctoral supervision, while universities provided broad education and degree frameworks. This relationship was especially important in chemistry because the training of a chemist requires both conceptual education and laboratory apprenticeship. The Academy's institutes helped preserve advanced laboratory cultures that could not be maintained by teaching institutions alone.

The connection with industry was another persistent feature. Czechoslovak chemical schools were often formed in dialogue with pharmaceuticals, petrochemistry, polymers, materials, analytical control, environmental monitoring, and chemical technology. This connection was shaped differently under socialism and after 1989. Under socialism, industry and Academy research were often linked through state planning and sectoral priorities. After 1989, cooperation increasingly depended on contracts, patents, licences, technology transfer, start-ups, and international innovation programmes. Yet the underlying fact remained: chemistry was one of the Academy fields most naturally positioned between fundamental knowledge and practical transformation. Its continuity was therefore strengthened by the fact that it could repeatedly demonstrate public and technological relevance without abandoning scientific depth.

The intellectual continuity of Czechoslovak chemical schools can also be seen in the recurring importance of structure. Organic chemistry studied molecular structure and synthesis; physical chemistry related structure to properties and processes; quantum chemistry explored electronic structure; polymer chemistry examined macromolecular architecture; analytical chemistry revealed structure through measurement; inorganic chemistry designed and characterised coordination and solid-state structures; chemical engineering translated molecular and phase behaviour into processes. This shared concern with structure gave Czech chemistry an internal coherence across institutes. It also allowed the field to move towards modern materials science, molecular biology, nanoscience, catalysis, and environmental chemistry. Continuity was therefore conceptual as well as institutional.

The symbolic significance of chemistry within the Academy was reinforced by its major personalities. Heyrovský represented international recognition and methodological originality. Šorm represented institution-building, organic synthesis, and the power of chemical leadership in the early Academy. Wichterle represented invention, polymer science, and the movement from laboratory discovery to global social use. Zahradník represented quantum

chemistry, theoretical sophistication, and post-socialist academic leadership. These figures should not be treated as isolated heroes detached from institutions. Their importance lies precisely in the way they crystallised broader schools and institutional possibilities. Through them, Czechoslovak chemistry became visible as a tradition capable of producing both scientific authority and public meaning.

The Academy's chemical continuity was therefore not a simple line from past to present. It was a layered process in which pre-war university traditions, wartime displacement, post-war reconstruction, socialist institutionalisation, reform hopes of the 1960s, normalisation, Velvet Revolution, Czech statehood, and European integration all left traces. The chemical institutes carried these traces in their names, buildings, research programmes, and memories of founders. Their development shows that institutional history is not only written through statutes and reforms. It is also written through compounds synthesised, instruments maintained, methods improved, students trained, patents filed, collaborations sustained, and scientific languages transmitted. Chemistry gives this history a particularly concrete materiality because its continuity is embedded in substances and experimental practices.

Thus, the continuities from Czechoslovak chemical schools into the Czech Academy of Sciences formed one of the strongest pillars of the Academy's modern identity. Organic chemistry and biochemistry, polarography and physical chemistry, macromolecular chemistry, chemical engineering, analytical chemistry, inorganic chemistry, catalysis, and materials research all carried forward traditions created under earlier institutional and political conditions. These traditions survived not because they were untouched by history, but because they were capable of being reworked after each rupture. The Czech Academy inherited them, reformed them, internationalised them, and placed them within a new framework of public research, European cooperation, and innovation. In this sense, chemistry demonstrates one of the central themes of the Academy's entire history: scientific continuity is not the absence of change, but the capacity of a research culture to preserve its deepest competencies while learning to operate in a transformed world.

2. Organic Chemistry, Polymers, Catalysis, and Materials

The chemical sciences of the Czech Academy of Sciences acquired their modern institutional form through a set of fields that were both intellectually deep and unusually close to practical transformation: organic chemistry, polymer science, catalysis, and materials research. These fields were not marginal applications of chemistry but central arenas in which the Academy demonstrated what a public research institution could do with matter at the molecular and supramolecular level. Organic chemistry gave Czech science the capacity to design, synthesise, and interpret complex molecules, including compounds with biological activity. Polymer science extended chemistry into macromolecular systems, soft matter, biomedical materials, and technological artefacts. Catalysis connected molecular understanding with energy, environmental protection, industrial processes, and sustainability. Materials research joined chemistry with physics, biology, engineering, and nanoscience, turning the study of substances into the deliberate creation of functional systems. Together, these fields made the Academy's chemistry one of its most visible bridges between fundamental science and the changing needs of society (*Akademie věd České republiky, n.d.*).

The institutional ecology of Academy chemistry is especially important here. Organic chemistry and biochemistry were concentrated most visibly in the Institute of Organic Chemistry and Biochemistry, macromolecular chemistry in the Institute of Macromolecular Chemistry, physical chemistry and catalytic research in the J. Heyrovský Institute of Physical Chemistry, chemical engineering and catalytic process science in the Institute of Chemical Process Fundamentals, and inorganic and materials chemistry in the Institute of Inorganic Chemistry. This distribution did not divide chemistry into isolated compartments. On the contrary, it created a network of neighbouring specialisations that could interact around shared questions: how molecules are built, how they react, how they assemble, how they transport charge or energy, how they bind other substances, how they behave in biological environments, and how they may be converted into useful materials. The Academy's strength in this area came from precisely this combination of specialisation and permeability. Each institute had its own tradition, but the strongest research questions often crossed institutional boundaries.

Organic chemistry occupied a privileged place in this constellation because it deals with the architecture of molecules. In the Academy context, organic chemistry was never merely a catalogue of reactions or a service discipline for other sciences. It was a mode of thinking about structure, transformation, stereochemistry, function, and biological relevance. The Institute of Organic Chemistry and Biochemistry developed its research profile at the interface of organic chemistry, biochemistry, medicinal chemistry, natural products chemistry, material-oriented chemistry, theoretical chemistry, analytical chemistry, molecular biology, and chemical biology (*Institute of Organic Chemistry and Biochemistry, n.d.*). Such breadth was not accidental. It reflected the fact that modern organic chemistry increasingly lives between the molecule and the living system, between synthetic design and biological function, between laboratory creativity and potential therapeutic use.

The tradition associated with František Šorm gave this organic-chemical culture a strong institutional foundation. Šorm's school had already linked organic synthesis with natural products and biologically active compounds, and this orientation helped the Institute of Organic Chemistry and Biochemistry move naturally towards biochemical and medicinal questions. In the post-war and socialist periods, this gave Czech chemistry a distinctive identity: it was rigorous in synthesis, attentive to structure, and open to biology. After 1989, this identity proved especially valuable because international chemistry increasingly rewarded research that could move across the boundaries of chemistry, biology, and medicine. The Academy's organic chemistry therefore did not have to reinvent itself completely. It had to modernise, internationalise, and reframe capacities that had already been cultivated over several generations.

The work of Antonín Holý became the most powerful modern example of this tradition. His research on modified nucleosides and nucleotides, particularly acyclic nucleoside phosphonates, showed how basic synthetic and medicinal chemistry could produce compounds of global medical significance. The story of tenofovir is especially revealing. Tenofovir was first synthesised by Holý, and its anti-HIV activity was later recognised through collaboration with Erik De Clercq and further development by Gilead Sciences and other partners (*Institute of Organic Chemistry and Biochemistry, n.d.*; *Gilead Sciences, 2011*). The institutional lesson is not simply that an Academy scientist contributed to important antiviral drugs. It is that a long-term research environment in organic chemistry made possible

discoveries whose practical significance could not be fully predicted at the moment of synthesis. This is one of the strongest arguments for the Academy's public research model.

Holý's work also changed the economic and symbolic position of chemistry within the Czech Academy. Successful compounds related to antiviral treatment created international visibility, technology-transfer experience, and resources that helped strengthen the Institute of Organic Chemistry and Biochemistry. The partnership with Gilead Sciences, including the establishment of the Gilead Sciences Research Centre at IOCB Prague, became a landmark in the relationship between Czech public research and global pharmaceutical development (*Gilead Sciences, 2006*; *Institute of Organic Chemistry and Biochemistry, n.d.*). This relationship should not be understood as the simple commercialisation of academic chemistry. Rather, it showed how a research institute could retain its identity as a basic-science institution while also participating in the long chain through which molecules become medicines. The Academy's chemistry thus entered a new phase in which discovery, licensing, international partnership, and institutional reinvestment became part of its history.

The organic chemistry of the Academy also extended beyond medicinal chemistry narrowly understood. Material-oriented organic chemistry, supramolecular chemistry, chemical biology, molecular recognition, fluorescence probes, bioactive molecules, and synthetic methodology all belonged to the broader landscape. Organic chemists became builders of molecular tools: compounds that could report on biological processes, alter cellular pathways, bind selectively to targets, organise into functional assemblies, or serve as precursors for new materials. This development reflected a global shift in chemistry from the preparation of substances as isolated products to the design of molecules as active participants in complex systems. In the Academy, this shift strengthened the links between organic chemistry and biochemistry, between chemical synthesis and imaging, between molecular design and materials science. It also helped move Czech chemistry from a nationally respected tradition to a more visibly international research culture.

The Institute of Organic Chemistry and Biochemistry became an especially clear example of how post-socialist scientific renewal could build on inherited strengths while changing institutional scale. Its contemporary identity as a leading research institution under the Czech Academy rests on research at the interface of chemical and biological sciences, but also on an organisational culture that supports group leaders, doctoral training, technology transfer, and international recruitment. The opening of IOCB Boston in 2024, the first overseas branch of a Czech Academy institute, symbolised this outward movement of Czech chemical science towards one of the world's central biomedical hubs (*Akademie věd České republiky, 2024*). Although this belongs partly to the later story of innovation and globalisation, it also reveals something about organic chemistry itself. A field once rooted in Czechoslovak laboratory schools had become capable of institutional presence in the global geography of drug discovery.

Polymer science formed a second major pillar of Academy chemistry. The Institute of Macromolecular Chemistry, founded by Otto Wichterle, gave Czech macromolecular research a durable institutional home and linked it to one of the country's most famous scientific-technological achievements: the soft contact lens. Yet the importance of polymers in the Academy cannot be reduced to this single invention, however significant it was. Polymer science opened a vast field between small-molecule chemistry and materials engineering. It asked how long chains, networks, gels, membranes, elastomers, conducting systems, and

biomacromolecular assemblies acquire properties that cannot be predicted simply by knowing the monomer. This made macromolecular chemistry both chemically specific and physically rich. It required synthesis, characterisation, theory, processing, morphology, rheology, and application to be considered together.

The Institute of Macromolecular Chemistry's contemporary profile shows this breadth. It focuses on synthetic polymers and benefits from the concentration of diverse polymer research under one institutional roof, with projects ranging from biomacromolecular systems for medical purposes to procedures for recycling and eliminating plastic waste (*Institute of Macromolecular Chemistry, n.d.*). This range is historically significant because it connects the older prestige of Wichterle's biomedical polymer work with contemporary problems of sustainability, circular economy, and polymer waste. The same field that once helped produce soft biomedical materials now confronts the environmental consequences of polymer civilisation. The Academy's polymer research therefore moves between promise and responsibility. It designs new materials, but it also studies how existing materials can be recycled, degraded, reused, or made safer.

Polymer chemistry also altered the relationship between chemistry and the human body. Hydrogels, biocompatible polymers, drug-delivery systems, tissue-contact materials, and responsive macromolecular structures showed that materials could be designed not only for mechanical or industrial purposes but for intimate biological environments. This was a profound change in the cultural meaning of chemistry. Matter was no longer only something manufactured outside the body; it could become a carefully designed interface with living tissue. The Academy's macromolecular chemistry was well suited to such work because it combined synthetic competence with physical characterisation and biomedical awareness. This helped place Czech polymer research within international debates on biomaterials, nanomedicine, soft matter, and molecular therapeutics.

At the same time, polymer science remained deeply connected to technological materials. Conducting polymers, polymer blends, membranes, coatings, self-organised block copolymers, electrolytes, and materials for energy storage placed macromolecular chemistry in contact with electronics, energy, photonics, and environmental technology. Research on conducting polymer materials for supercapacitor applications, for example, illustrates how polymer morphology, surface area, mechanical properties, and electrochemical behaviour may be brought together in one research problem (*Institute of Macromolecular Chemistry, n.d.*). Such work shows that polymers are not passive plastics in the everyday sense. They can be active materials, capable of transporting charge, storing energy, responding to stimuli, or forming structured environments for other chemical processes. In this sense, macromolecular chemistry became a central route through which the Academy entered advanced materials science.

Catalysis represented a third pillar and perhaps the most conceptually strategic link between chemistry and the modern world. A catalyst changes the path of a chemical reaction without being consumed in the ordinary stoichiometric sense. This simple definition hides enormous complexity. Catalysis involves surfaces, active sites, intermediates, reaction mechanisms, kinetics, thermodynamics, diffusion, electronic structure, reactor design, and often uncertain relations between laboratory performance and industrial operation. In the Academy, catalytic research developed in both physical chemistry and chemical process fundamentals. The J. Heyrovský Institute of Physical Chemistry approached catalysis through molecular-level

understanding, electrochemistry, nanocatalysis, photocatalysis, surface science, and materials. The Institute of Chemical Process Fundamentals linked catalysis to reaction engineering, catalyst development, catalytic reactors, microstructure characterisation, and chemical production (*J. Heyrovský Institute of Physical Chemistry, n.d.*; *Institute of Chemical Process Fundamentals, n.d.*).

This dual location of catalysis was a strength. At the level of physical chemistry, the central question is often why a catalyst works: which surface sites are active, how charge is transferred, how intermediates form, how light or electric potential changes reactivity, and how nanoscale structure influences performance. At the level of chemical engineering, the question becomes how catalytic reactions can be made reliable, selective, scalable, and environmentally acceptable. The Academy's institutional structure allowed both questions to be asked. Catalysis could remain intellectually fundamental while also being connected to responsible chemical production, environmental protection, and industrial relevance. This is precisely the kind of balance that public research institutions are meant to sustain.

The J. Heyrovský Institute's contemporary orientation towards molecules, materials, and processes reflects this catalytic role. Its research includes areas such as electrochemistry at the nanoscale, nanocatalysis, low-dimensional systems, computational chemistry, and materials related to energy conversion and storage (*J. Heyrovský Institute of Physical Chemistry, n.d.*). Catalytic and electrocatalytic research became especially important in the context of energy transition. Processes such as water splitting, hydrogen production, carbon dioxide conversion, oxygen reduction, fuel synthesis, pollutant degradation, and energy storage all depend on advances in catalytic materials and mechanistic understanding. Academy chemists therefore entered debates that were not only scientific but also civilisational. The question of catalysis became linked to how societies might move beyond fossil carbon while maintaining chemical production, mobility, agriculture, and energy security.

The importance of catalysis for environmental protection is equally clear. Heterogeneous photocatalysis, catalytic degradation of pollutants, catalytic conversion of waste streams, and nanostructured materials for remediation connect chemical research to the public interest. NanoEnviCz and related research infrastructures and projects illustrate how nanomaterials, heterogeneous catalysis, photocatalysis, sensing, pollutant monitoring, and environmental technologies could be integrated within Academy-related research (*J. Heyrovský Institute of Physical Chemistry, n.d.*). This development shows how catalysis shifted from a classical industrial topic to a broader field of sustainable chemistry. It also demonstrates that environmental science in the Academy cannot be separated from chemistry. The protection of air, water, soil, and energy systems often begins with molecular transformation.

The Institute of Chemical Process Fundamentals contributed a complementary process perspective. Its Department of Catalysis and Reaction Engineering traditionally undertakes research in heterogeneous catalysis engineering, including catalyst development, catalytic reactor design, phenomenological kinetics, and catalyst microstructure characterisation (*Institute of Chemical Process Fundamentals, n.d.*). This field is vital because many catalytic discoveries fail when they move from elegant laboratory conditions to realistic process environments. Reactors impose constraints: heat transfer, mass transfer, deactivation, pressure, residence time, selectivity, safety, and scale. The Academy's process chemistry therefore served as a bridge between molecular insight and technological realism. It helped

ensure that catalysis remained connected not only to what is chemically possible, but also to what can be performed, controlled, measured, and potentially scaled.

Materials research was the 4th major pillar and the field in which all the previous domains converged. Modern materials science is not simply chemistry, physics, or engineering, but a structured conversation among them. Organic molecules can become functional materials; polymers can become biomedical interfaces or electronic systems; catalysts are often materials with controlled surfaces; inorganic compounds can become porous frameworks, nanostructures, membranes, or sensors; analytical methods make materials visible and comparable. The Czech Academy's Section of Chemical Sciences explicitly places inorganic chemistry, physical chemistry, organic chemistry, macromolecular chemistry, analytical chemistry, and chemical process fundamentals within one institutional landscape (*Akademie věd České republiky, n.d.*). This arrangement made materials research a natural cross-cutting field.

Inorganic chemistry contributed especially through the preparation and characterisation of new compounds and materials. Areas such as coordination compounds, boranes, zeolites, metal oxides, layered materials, porous materials, and metal-organic frameworks linked molecular design to solid-state function. Metal-organic frameworks are a good example because they combine organic linkers with metal centres to create porous crystalline structures with possible applications in gas storage, separation, heterogeneous catalysis, sensing, and drug delivery (*Demel, n.d.*). Such materials blur older boundaries. They are inorganic and organic, molecular and solid, structural and functional. Their development reflects the broader movement of chemistry towards designable architectures, where the aim is not only to discover substances but to build matter with targeted behaviour.

The AMULET project, led by the J. Heyrovský Institute of Physical Chemistry, offers a useful example of how materials research has become a multi-institutional Academy concern. It focuses on advanced multiscale materials for key enabling technologies, connecting nanomaterials, biological interactions, electrochemical and optical sensors, electro-photochemical catalysis, pollutant removal, and energy conversion and storage (*J. Heyrovský Institute of Physical Chemistry, 2023*). The project involves several Academy institutes and universities, including the Institute of Organic Chemistry and Biochemistry, the Institute of Photonics and Electronics, the Institute of Physics, the Nuclear Physics Institute, Charles University, and the University of Chemistry and Technology in Prague. This is important because it shows that materials science is no longer a single-institute speciality. It has become an organising framework through which chemistry, physics, nanoscience, instrumentation, and biomedical research can collaborate.

Analytical chemistry gave these fields the methods needed to know what had actually been made. The Institute of Analytical Chemistry developed theoretical background, applications, and instrumentation of separation and spectroscopic methods; its technologies include microfluidics and nanomaterials, while its separation research uses electric fields, sorption, fluid flow, force fields, chemical reactions, and combinations of these driving forces (*Institute of Analytical Chemistry, n.d.*). In the context of organic chemistry, polymers, catalysis, and materials, analytical chemistry is not auxiliary. It is epistemologically central. A new molecule, polymer, catalyst, or material becomes scientifically meaningful only when its composition, structure, purity, morphology, dynamics, and behaviour can be measured. The Academy's analytical capacities therefore helped turn chemical imagination into reliable knowledge.

The growth of materials research also increased the importance of computation and modelling. Catalytic mechanisms, polymer dynamics, molecular recognition, electronic structure, adsorption, energy barriers, and materials stability often require theoretical interpretation alongside experiment. The Academy's chemical institutes, especially the J. Heyrovský Institute, maintained strong traditions in theoretical and computational chemistry, which helped connect chemical intuition with quantitative models. This is historically significant because it shows that modern chemistry is no longer divided neatly between the "wet laboratory" and abstract theory. It is increasingly a field of integrated workflows: synthesis, measurement, modelling, prediction, and redesign. The Academy's institutional scale allowed these workflows to be cultivated over long periods.

The post-socialist transformation of Czech chemistry gave these fields new institutional conditions. Under the Czechoslovak Academy, chemistry had been supported by state interest in industry, medicine, and technology, but it was also shaped by central planning, limited access to Western equipment, political constraints on travel, and uneven contact with global research. After 1989 and especially after the creation of the Czech Academy in 1993, chemical institutes had to adapt to grant competition, international evaluation, European projects, new intellectual property regimes, and more open cooperation with universities and industry. Organic chemistry, polymers, catalysis, and materials were particularly well suited to this transformation because their international languages were already strong and their practical relevance was visible. They could demonstrate excellence through publications, patents, licences, collaborations, and technological partnerships.

The relation between fundamental research and application remained delicate. In organic chemistry, a molecule synthesised for conceptual reasons may later become a therapeutic candidate. In polymer science, a material designed to test a physical principle may later become useful in medicine or energy storage. In catalysis, mechanistic insight may eventually produce cleaner industrial processes. In materials research, a new structure may first be valuable because it reveals a principle of assembly, not because it immediately enters a product. The Academy's role was to preserve this uncertainty as a productive space. It did not have to force every project into immediate commercial usefulness, but it also did not isolate chemistry from practical consequences. This balance became one of the defining features of the Academy's chemical sciences.

These fields also shaped the Academy's relations with industry. Chemistry naturally produces substances, methods, materials, processes, and intellectual property that may attract industrial partners. The IOCB–Gilead relationship is the most famous case, but it belongs to a broader pattern in which Academy chemistry interacts with pharmaceuticals, biotechnology, polymers, environmental technologies, analytical instrumentation, catalysis, and materials processing. Such cooperation is valuable only when the Academy retains strong internal science. Companies need public research institutions not because they duplicate industrial laboratories, but because they sustain deep expertise and exploratory work that the market alone may underfund. The Academy's chemistry therefore contributed to innovation precisely by remaining scientifically ambitious.

The educational role of these chemical fields was also substantial. Academy institutes trained doctoral students, hosted postdoctoral researchers, cooperated with universities, and offered laboratory environments that complemented formal teaching. Organic synthesis, polymer characterisation, catalytic testing, spectroscopic measurement, microfluidic analysis, and

materials preparation cannot be learned adequately through theory alone. They require apprenticeship in laboratories, exposure to failures, familiarity with instruments, and participation in research groups. Through this training function, the Academy helped reproduce the national chemical community. Its institutes were not only repositories of knowledge but also schools of scientific practice.

The cultural significance of Academy chemistry lies in its ability to make the transformation of matter visible as a public achievement. Heyrovský's polarography, Wichterle's contact lenses, Holý's antivirals, polymer biomaterials, catalytic energy systems, and nanostructured materials all show chemistry as a field where invisible molecular arrangements can enter public life. This gave chemistry a particular narrative power within the history of the Academy. It could demonstrate that fundamental research matters not only through abstract prestige but through medicines, materials, instruments, cleaner processes, and technological possibilities. At the same time, its most important achievements depended on long-term basic science. The public success of chemistry therefore reinforced, rather than weakened, the argument for autonomous research.

Organic chemistry, polymers, catalysis, and materials also show how the Academy's chemical institutes moved from national traditions to global scientific conversations. Their work touched antiviral therapy, sustainable energy, circular polymer economy, green catalysis, nanomaterials, biomedical interfaces, environmental monitoring, and advanced analytical methods. These are not narrowly Czech problems, but the Academy approached them through Czech institutional traditions and research capacities. This combination gave the fields their historical specificity. Czech Academy chemistry became international not by abandoning its past, but by translating inherited schools into contemporary research questions. The result was a modern chemical science that remained institutionally rooted while scientifically open.

Thus, organic chemistry, polymer science, catalysis, and materials research formed the dynamic core of the Academy's chemical sciences. They connected molecular design with biological function, macromolecular structure with biomedical and environmental responsibility, catalytic mechanisms with energy and industrial transformation, and materials architecture with the technological challenges of the 21st century. Their history shows that Academy chemistry was never only a continuation of Czechoslovak laboratory schools, nor merely an instrument of innovation policy. It was a living research culture in which fundamental curiosity, experimental discipline, institutional continuity, and practical consequence repeatedly met. Through these fields, the Czech Academy of Sciences became a national custodian of chemical expertise and an international participant in the effort to understand, design, and responsibly use matter.

3. Chemistry between Fundamental Science and Innovation

Chemistry within the Czech Academy of Sciences has always occupied a position between two intellectual worlds. On the one hand, it belongs to the sphere of fundamental knowledge, where the aim is to understand molecular structure, reactivity, bonding, phase behaviour, catalysis, macromolecular organisation, and the physical principles of chemical change. On the other hand, chemistry is one of the sciences most naturally drawn towards application because its objects are substances, materials, processes, drugs, surfaces, analytical methods, and technologies that can enter public life directly. This dual position makes

chemistry especially important for understanding the modern Academy's institutional identity. It shows that basic research and innovation are not two separate stages arranged in a mechanical sequence. They are often intertwined from the beginning, although their rhythms, risks, and languages differ. The Czech Academy's chemical institutes demonstrate this interdependence with unusual clarity: the same research culture that investigates molecules for their own scientific interest may later produce antivirals, biomaterials, catalysts, separation methods, environmental technologies, or intellectual property of global value (*Akademie věd České republiky, n.d.*; *Strategy AV21, n.d.*).

This position between fundamental science and innovation was not created only after 1989. It has deeper roots in the history of Czechoslovak chemistry, where university traditions, industrial chemistry, pharmaceutical research, polymer science, electrochemistry, and chemical engineering were never fully isolated from one another. Under the Czechoslovak Academy of Sciences, chemistry was supported partly because it could serve industrial modernisation, agriculture, energy, medicine, and strategic technologies. Yet the best Academy chemistry did not simply become an auxiliary of production. It retained a strong commitment to mechanisms, molecular design, structure–property relations, and methodological originality. The post-socialist Academy inherited precisely this ambivalent but productive tradition. Its task was to protect the autonomy of chemical research while creating new, more transparent, internationally oriented, and legally sophisticated pathways from laboratory discovery to social use.

The contemporary structure of the Academy's chemical sciences reflects this dual mission. The Section of Chemical Sciences includes the Institute of Analytical Chemistry, the Institute of Inorganic Chemistry, the Institute of Chemical Process Fundamentals, the J. Heyrovský Institute of Physical Chemistry, the Institute of Macromolecular Chemistry, and the Institute of Organic Chemistry and Biochemistry. The Academy's own description of this section links theoretical and quantum chemistry with electrochemistry and catalysis, inorganic compounds and materials, organic chemistry and biochemistry, anti-viral medicaments, new polymers for biomedicine, separation techniques, spectral methods, thermodynamics, phase behaviour, reacting systems, and modern separation methods (*Akademie věd České republiky, n.d.*). This list is more than an administrative catalogue. It reveals a research landscape in which fundamental explanation and practical orientation are present within the same institutional vocabulary. Chemistry in the Academy is therefore not divided into "pure" and "applied" camps; rather, it is organised around fields in which the pure and the applied continually reshape one another.

The relation between chemistry and innovation is particularly visible in medicinal chemistry. The Institute of Organic Chemistry and Biochemistry represents the Academy's most internationally recognised example of how fundamental organic and biochemical research can become part of global therapeutic development. Its mission is rooted in basic research at the interface of chemistry and biology, including chemical biology, medicinal chemistry, organic and materials chemistry, natural substances, biochemistry, molecular biology, physical chemistry, theoretical chemistry, and analytical chemistry (*Institute of Organic Chemistry and Biochemistry, n.d.*). This breadth is important because drug discovery rarely emerges from one discipline alone. It requires molecular synthesis, biological testing, mechanistic understanding, pharmacological imagination, intellectual property protection, and collaboration with partners capable of development. The Academy's role is not to replace the

pharmaceutical industry, but to create the conditions in which original molecular ideas can arise before commercial logic fully knows what to ask for.

Antonín Holý's work remains the most powerful example of this logic. His research on nucleotide analogues was fundamentally chemical, rooted in synthetic design and the exploration of biologically active compounds. Yet compounds developed from this line of research, including cidofovir, tenofovir, and adefovir, later became part of medicines used against serious viral diseases, especially HIV/AIDS and hepatitis B (*Akademie věd České republiky, 2023*; *Institute of Organic Chemistry and Biochemistry, n.d.*). The importance of this case is not simply that it produced successful drugs. It shows the long and uncertain path by which basic molecular research may acquire human meaning. A molecule synthesised within an academic research programme becomes medically useful only through testing, development, modification, regulatory processes, production, and international partnership. The Academy's contribution lies at the beginning of this chain, where scientific creativity is most necessary and commercial certainty is weakest.

The partnership between IOCB Prague and Gilead Sciences transformed this scientific achievement into a durable institutional model. The collaboration began in the 1990s, when Gilead licensed several nucleotide analogue compounds discovered by Holý and his colleagues. In 2006, the Gilead Sciences Research Centre was established at IOCB Prague, and the partnership was later renewed, including a further extension announced in 2023 to support projects in virology, inflammation, and oncology (*Akademie věd České republiky, 2023*; *Gilead Sciences, 2006*; *Gilead Sciences, 2011*). This model is historically important because it created a bridge between Czech public research and global biopharmaceutical development without turning the Academy institute into a company laboratory. IOCB remained an academic institute, but it acquired a sophisticated innovation culture: licensing, translational collaboration, reinvestment, postdoctoral support, and strategic partnership. In this way, chemistry became one of the fields through which the Academy learned how to transform scientific success into institutional capacity.

Technology transfer at IOCB was professionalised through IOCB Tech. The institute decided in 2007 to establish its own technology transfer office; IOCB TTO was founded in 2009, began operations in 2010, and was renamed IOCB Tech in 2017 (*Institute of Organic Chemistry and Biochemistry, n.d.*). Its tasks include identifying commercially promising projects, analysing market potential and patentability, protecting intellectual property, supporting project development, finding commercial partners, and negotiating licensing agreements. This institutional development matters because it shows that innovation cannot be left to accidental contacts between individual scientists and companies. It requires professional expertise in law, business, patent strategy, market assessment, and project management. The creation of IOCB Tech therefore marked a new stage in the Academy's chemical history: the emergence of specialised structures designed to translate research results while preserving the institute's basic-science mission.

The significance of IOCB Tech also lies in its broader ecosystem. The development of i&i Prague, early-stage funding initiatives, and later translational facilities such as PharmTheon indicated that the institute's innovation model expanded beyond individual licensing cases (*Institute of Organic Chemistry and Biochemistry, n.d.*). This ecosystem is not merely administrative decoration around science. It changes how researchers imagine the possible future of their discoveries. A chemist can remain focused on molecules and mechanisms while

knowing that a professional structure exists to evaluate patentability, identify partners, and support early translation. Such an arrangement reduces the danger that promising academic discoveries will remain unused because scientists lack commercial experience. It also reduces the opposite danger: that researchers will prematurely commercialise weak ideas without proper scientific grounding.

At the level of the whole Academy, technology transfer is supported by CeTTAV, the Technology Transfer Centre of the Czech Academy of Sciences. CeTTAV provides guidance to Academy institutes on patents, inventions, prototypes, testing, commercialisation staff, investors, and spin-off companies (*Akademie věd České republiky, 2022*). The existence of such a centre shows that the Academy has recognised knowledge and technology transfer as a strategic task. Yet its role also reveals a delicate institutional balance. The Academy must help researchers apply their work, but it must not convert every research question into a business proposal. Technology transfer is most valuable when it follows strong science and helps it reach society; it becomes harmful when it pressures scientists to overpromise utility. In chemistry, this distinction is especially important because the path from molecular discovery to product is long, expensive, and uncertain.

Strategy AV21 gives this balance a broader public framework. Its motto, "Top research in the public interest", places the Academy's research within social challenges while preserving the importance of excellence (*Strategy AV21, n.d.*). For chemistry, this is a particularly suitable formulation. Public interest does not mean that every chemical project must immediately solve a visible social problem. Rather, it means that chemical knowledge, methods, and infrastructures should be available for problems that society cannot solve without science: disease, energy transition, food security, environmental pollution, materials scarcity, waste, climate adaptation, and technological resilience. Strategy AV21 therefore helps articulate why fundamental chemistry belongs in a public academy. It is not justified only by historical prestige or internal disciplinary curiosity, but by its capacity to generate knowledge that may become socially decisive.

The connection between chemistry and public interest appears strongly in antiviral and medicinal research. The IOCB–Gilead case demonstrated how basic chemical research could affect global health, but it also revealed the limits of academic control over later stages of drug development. Once a compound enters industrial and clinical pathways, questions of access, price, regulation, production, and global distribution become central. These questions do not cancel the scientific achievement, but they remind us that innovation is not identical with public benefit unless institutional and social systems carry it further. The Academy's responsibility lies in the scientific and early translational stages, where it can create molecules, methods, and knowledge. The broader public impact depends on partners, states, health systems, and international policies. This makes chemistry an especially clear example of how science enters society through complex chains rather than direct linear transfer.

Polymer science offers another model of chemistry between fundamental research and innovation. The Institute of Macromolecular Chemistry, founded by Otto Wichterle, inherited one of the most famous examples of Czech chemical innovation: soft contact lenses. Yet its contemporary importance extends far beyond that achievement. Modern polymer research deals with synthetic polymers, biomacromolecular systems, biomedical materials, responsive systems, membranes, conducting polymers, drug-delivery carriers, recycling, and plastic-waste problems (*Institute of Macromolecular Chemistry, n.d.*). These topics show how the

same field can serve human health, materials technology, environmental responsibility, and fundamental macromolecular understanding. Polymer science is therefore innovation-oriented by nature, but its innovations depend on deep knowledge of chain structure, morphology, phase behaviour, mechanics, swelling, degradation, and molecular architecture.

The Academy's polymer research also demonstrates that innovation can take the form of responsibility, not only invention. The 20th century celebrated polymers as symbols of modernity: flexible, cheap, durable, manufacturable, and adaptable. The 21st century has had to confront the environmental consequences of that same durability. Research on polymer recycling, degradability, separation, and waste reduction belongs to a different innovation culture from the heroic invention of a single successful product. It is slower, more systemic, and often less visible to the public. Yet it may be equally important. The Academy's role is to study polymers not only as materials to be created, but also as materials to be managed across their life cycle. In this sense, chemistry becomes part of environmental governance.

Catalysis provides another powerful example of the relation between fundamental science and innovation. A catalyst is not merely a convenient technical tool; it is a molecular or material system that reshapes chemical possibility. Understanding catalysis requires physical chemistry, surface science, electronic structure, reaction kinetics, thermodynamics, spectroscopy, modelling, and often engineering. At the J. Heyrovský Institute of Physical Chemistry, catalytic and electrocatalytic research connects electrochemistry, nanomaterials, energy conversion, and chemical physics. At the Institute of Chemical Process Fundamentals, catalysis is linked with reaction engineering, reactor design, catalyst microstructure, kinetics, and chemical process science (*Institute of Chemical Process Fundamentals, n.d.*; *J. Heyrovský Institute of Physical Chemistry, n.d.*). This dual institutional location reflects the nature of catalysis itself: it is both a fundamental mechanism and a practical pathway to cleaner and more efficient chemical transformation.

The innovation potential of catalysis is especially clear in the context of energy and sustainability. Hydrogen production, carbon dioxide conversion, pollutant degradation, fuel cells, batteries, ammonia synthesis, selective oxidation, biomass conversion, and chemical recycling all depend on catalytic understanding. However, the route from catalytic discovery to usable technology is rarely direct. A catalyst that works in a small laboratory test may fail under realistic operating conditions because of deactivation, poisoning, mass-transfer limitations, thermal instability, or cost. The Academy's role is to study these problems without reducing them to engineering routine. It can investigate mechanism and performance together, thereby creating knowledge that is both intellectually robust and technologically meaningful. Catalysis thus shows why fundamental chemistry is indispensable for credible innovation in energy and environmental technologies.

Chemical engineering within the Academy adds another dimension to this picture. The Institute of Chemical Process Fundamentals deals with thermodynamics, phase behaviour, multiphase reacting systems, separation methods, catalysis, aerosol processes, environmental engineering, and process intensification (*Akademie věd České republiky, n.d.*; *Institute of Chemical Process Fundamentals, n.d.*). Such research is close to practical needs, but it remains scientifically demanding because real chemical processes involve complexity: mixtures, phases, interfaces, turbulent flows, heat transfer, mass transfer, competing reactions, and scale effects. Innovation here does not usually appear as a single molecule or patent. It appears as a better process, a cleaner separation, a more efficient reactor, a more

accurate model, or a safer technological route. The Academy's contribution is to provide the fundamental understanding that makes such improvements possible.

Analytical chemistry shows how innovation may also be methodological. The Institute of Analytical Chemistry develops methods and instrumentation for separation, spectral analysis, microfluidics, nanomaterials, bioanalysis, environmental monitoring, and health-related research (*Institute of Analytical Chemistry, n.d.*). Analytical methods are often invisible to the wider public because they do not always appear as final products. Yet they are indispensable to modern science and society. Without analytical chemistry, one cannot reliably detect pollutants, identify metabolites, characterise materials, monitor industrial processes, verify drug purity, study biological samples, or compare environmental conditions. Innovation in analysis therefore expands the capacity of other fields to know and act. In this sense, analytical chemistry is one of the quiet infrastructures of modern public knowledge.

The Academy's inorganic and materials chemistry further broadens the meaning of innovation. New inorganic compounds, boranes, coordination systems, porous materials, zeolites, metal oxides, nanomaterials, and hybrid organic–inorganic structures can be important for catalysis, sensing, separation, energy storage, drug delivery, photochemistry, and environmental applications. Such materials often emerge from fundamental questions about bonding, structure, reactivity, and stability. Their practical value may become clear only later, when a material's porosity, surface chemistry, optical properties, or electrochemical behaviour is linked to a specific use. This illustrates again the non-linear relationship between discovery and application. Chemistry's innovation capacity is often strongest when researchers are free to explore structures whose future utility is not yet obvious.

Materials research also forces chemistry to collaborate with physics, biology, engineering, and computation. The Academy's work on nanomaterials, electrochemical sensors, catalysts, biomedical materials, and energy-related systems cannot be contained within a single discipline. The AMULET project on advanced multiscale materials, led by the J. Heyrovský Institute of Physical Chemistry and involving several Academy and university partners, is a good example of this interdisciplinary direction (*J. Heyrovský Institute of Physical Chemistry, 2023*). Such projects show that innovation increasingly occurs at interfaces: between molecule and material, material and device, device and biological system, system and environment. The Academy's multi-institute structure is well suited to this type of work because it can bring together specialised expertise without forcing all research into one administrative unit.

The innovation role of chemistry also depends on infrastructures. Laboratories for synthesis, spectroscopy, microscopy, chromatography, mass spectrometry, catalysis testing, polymer characterisation, clean preparation, computational modelling, and biological screening are not simple background conditions. They shape the questions that can be asked and the reliability of the answers. Modern chemistry is increasingly instrument-intensive, and therefore institutional capacity matters. A small research group may have an original idea, but without access to suitable instruments and technical staff, that idea may remain untested. The Academy's chemical institutes provide precisely these conditions of possibility. They maintain laboratories whose value extends beyond individual projects and across generations of researchers.

This infrastructural dimension also explains why public research remains important even in fields attractive to industry. Companies may invest heavily in late-stage development, optimisation, production, and marketable technologies, but they often depend on public

research for exploratory science, risky hypotheses, early-stage methods, and specialised expertise. The Academy's chemical institutes create knowledge before it is obvious where the market lies. They also train people who later move into companies, hospitals, regulatory institutions, and universities. Their contribution to innovation is therefore broader than patents or licences alone. It includes human capital, methods, standards, instruments, interpretative frameworks, and expert communities.

Nevertheless, patents and licences are part of the modern Academy's chemical history. The IOCB case showed how intellectual property can become a mechanism for reinvesting scientific success into research. Licensing income, when governed responsibly, can support new laboratories, fellowships, technology transfer, and risk-taking in early-stage research. This creates a virtuous circle: basic research produces valuable knowledge; successful transfer generates resources; those resources strengthen the conditions for further basic research. The danger, however, is that exceptional success may create unrealistic expectations. Not every field can or should produce a tenofovir-like story. A mature Academy must value both spectacular transfer and slow, less visible research whose impact may be methodological, educational, environmental, or long-term.

The post-1989 period changed the language through which these issues were discussed. Under state socialism, "application" was often framed through planned economy priorities, industrial ministries, and state research tasks. After 1989, innovation came to be discussed through grants, patents, licences, spin-offs, European projects, private partners, intellectual property, and technology transfer offices. This change was not merely terminological. It altered incentives, institutional structures, and professional roles. Chemists now had to navigate a world in which publication, patenting, collaboration, and commercialisation could interact in complicated ways. The Academy's challenge was to create rules and support systems that allowed research to remain open and excellent while also protecting discoveries capable of application.

This challenge also has an ethical dimension. Chemistry can create medicines, diagnostic methods, clean processes, and sustainable materials, but it can also produce substances and technologies with environmental, health, or security risks. The Academy's public mission requires that innovation be judged not only by commercial value but also by safety, responsibility, transparency, and public benefit. In medicinal chemistry, this includes responsible collaboration and attention to health needs. In polymer science, it includes waste, toxicity, and life-cycle consequences. In catalysis and process chemistry, it includes emissions, energy use, and environmental impact. In analytical chemistry, it includes reliable evidence for public decision-making. The Academy's chemical innovation is therefore inseparable from scientific integrity and civic responsibility.

The connection between chemistry and innovation also affects career structures. Young chemists increasingly need to understand not only synthesis, analysis, modelling, and publication, but also collaboration with biologists, physicists, clinicians, engineers, patent specialists, and industrial partners. This does not mean that every chemist must become an entrepreneur. It means that the research environment has become more complex. Academy institutes provide training in this complexity through doctoral supervision, interdisciplinary projects, infrastructure access, and exposure to international networks. The Academy's educational role therefore includes not only the transmission of chemical knowledge but also

the formation of researchers capable of moving between fundamental questions and possible applications.

Internationalisation is central to this movement. The Academy's chemical institutes publish in international journals, participate in European projects, recruit foreign researchers, collaborate with companies and universities abroad, and increasingly situate their work within global challenges. IOCB's branch in Boston symbolises this outward movement in the field of chemical biology and drug discovery (*Akademie věd České republiky, 2024*). The point is not simply national prestige. It shows that Czech Academy chemistry can operate in international innovation ecosystems while remaining institutionally rooted in Prague and in the Czech public research tradition. This is an important form of post-socialist scientific maturity: not emigration of talent alone, but international presence through institutional agency.

At the same time, the Academy must avoid reducing innovation to global competitiveness only. Chemistry matters also for national and regional needs: environmental monitoring in Czech landscapes, materials expertise for domestic industry, analytical support for public institutions, collaboration with hospitals, and education of Czech students. The Academy's innovation role is therefore both global and local. It contributes to international medicine and materials science, but it also strengthens the scientific capacity of Czech society. This double orientation is historically important. Since the 19th century, Czech scientific institutions have carried a national cultural mission. In the 21st century, that mission is no longer defined only by national language or intellectual emancipation, but also by the capacity to provide knowledge for a complex society.

The relationship between fundamental science and innovation in Academy chemistry is therefore best understood as a continuum rather than a pipeline. The pipeline metaphor suggests that basic science enters at one end and products leave at the other. Real chemical innovation is less linear. A practical problem may inspire fundamental research; a fundamental discovery may remain unused for decades; a failed application may produce new theory; a method developed for one field may transform another. The Academy's institutional role is to sustain this non-linearity. It must allow chemists to ask questions without knowing their final use, while also ensuring that usable discoveries are not lost through institutional inertia.

The chemical sciences also demonstrate how innovation can reinforce scientific autonomy rather than threaten it. Successful transfer can provide resources, visibility, confidence, and societal trust. It can show that public investment in basic research produces value that cannot be planned in advance. However, autonomy is reinforced only when transfer supports research rather than dictating it. The Academy's strongest chemical examples show this distinction clearly. Holý's antiviral compounds arose from serious academic chemistry; polymer and catalytic innovations arise from deep structural and mechanistic work; analytical technologies arise from methodological expertise. The lesson is not that chemistry should chase application, but that excellent chemistry creates the possibility of application precisely because it is intellectually serious.

The public narrative of Academy chemistry therefore needs to be carefully balanced. It should celebrate successful drugs, materials, patents, and technologies, but it should also explain the invisible decades of research that made them possible. It should value innovation, but not turn innovation into a narrow market slogan. It should show that chemistry serves society not only when it produces a product, but also when it produces methods, standards, trained people, safety knowledge, environmental evidence, and conceptual understanding. In this respect,

chemistry is one of the best fields through which to explain the Academy's public mission. It makes the benefits of basic research tangible without reducing science to utility.

The modern Academy's chemical institutes thus stand at a historically meaningful crossroads. They carry Czechoslovak scientific traditions, but they operate in a European and global research environment. They pursue fundamental questions, but they also build technology-transfer systems. They create molecules and materials, but they also address health, sustainability, energy, environment, and industrial transformation. They cooperate with companies, but they must preserve public scientific responsibility. This crossroads is not a temporary difficulty. It is the normal condition of advanced chemistry in the 21st century. The Academy's achievement is not that it has escaped this condition, but that it has learned to work within it creatively.

Thus, chemistry in the Czech Academy of Sciences became one of the clearest arenas in which the relation between fundamental science and innovation was negotiated. Organic chemistry, polymer science, catalysis, analytical methods, inorganic materials, and chemical engineering all show that innovation is not external to academic chemistry but grows from its deepest forms of knowledge. At the same time, the Academy's experience demonstrates that useful outcomes depend on institutions: laboratories, research schools, technology-transfer offices, international partnerships, public strategies, intellectual property systems, and ethical responsibility. The chemical sciences therefore reveal a central truth about the modern Academy. Its public value does not lie in choosing between curiosity and usefulness, but in sustaining the research cultures through which curiosity may eventually become medicine, material, method, process, evidence, or public good.

Mathematics, Informatics, and Theoretical Research

1. Mathematical Institutes and Traditions

Mathematics occupies a distinctive position in the history of the Czech Academy of Sciences because it belongs at once to the most abstract sphere of knowledge and to the deepest infrastructure of modern science. It does not require the same visible apparatus as high-energy physics or plasma research, yet its institutional importance is no less profound. Mathematics gives form to physical theory, numerical modelling, computer science, statistics, optimisation, information theory, control, cryptography, data analysis, and many of the analytical languages through which contemporary science understands complex systems. Within the Academy, mathematics therefore developed not merely as a discipline among others, but as a foundational culture of exact reasoning. Its traditions reached back before the Czechoslovak Academy of Sciences, passed through the institutional construction of the socialist period, and were then reworked within the Czech Academy after 1993. The history of mathematical institutes in the Academy is thus a history of continuity, abstraction, institutional restraint, and expanding relevance (*Rákosník & Rozložník, 2021*; *Akademie věd České republiky, n.d.*).

The Academy's contemporary structure places mathematics, physics, and computer science within the same broad research area. This arrangement is not accidental. The Academy

describes this domain as covering not only fundamental physical research but also logic, topology, differential equations and their numerical solutions, statistical methods, neural networks, optimisation, and numerical modelling (*Akademie věd České republiky, n.d.*). Such a description captures the essential institutional character of mathematics in the Czech Academy: it is simultaneously autonomous and relational. It has its own internal problems, styles of proof, schools, and journals, yet it also supplies conceptual and computational instruments to neighbouring fields. Mathematics in the Academy therefore cannot be treated as a purely service discipline, but neither can it be separated from the wider scientific system. It is both a realm of pure thought and a condition of advanced empirical research.

The central institution of this tradition is the Institute of Mathematics of the Czech Academy of Sciences. Its history reaches back to 1947, when it was established as the Institute for Mathematics of the Czech Academy of Sciences and Arts, with Eduard Čech as initiator and first director (*Rákosník & Rozložník, 2021*). This date is important because it places the origins of the Academy's mathematical institute before the formal creation of the Czechoslovak Academy of Sciences in 1952. Mathematics therefore entered the socialist Academy with an already developing institutional identity. The institute was reorganised and incorporated into the Czechoslovak Academy in 1953, became part of the Czech Academy after the dissolution of Czechoslovakia in 1993, and was transformed into a public research institution in 2007 together with other Academy institutes (*Rákosník & Rozložník, 2021*). This genealogy reveals a central feature of Czech mathematical history: the discipline was repeatedly reorganised by political and administrative change, but its intellectual continuity was carried by schools, seminars, publications, and individual authority.

Eduard Čech was the decisive founding figure in this institutional story. He was not only a mathematician of international standing, associated with topology, projective differential geometry, Čech cohomology, and the Stone–Čech compactification, but also an organiser of Czech mathematical life. His pre-war topological seminar created a new form of collective mathematical work in Czechoslovakia, where research ceased to be merely the isolated activity of individual scholars and became the shared labour of a school. The disruption caused by the Nazi closure of Czech universities in 1939 interrupted this development, but did not erase it. After the war, Čech moved to Prague, became professor at Charles University, and played a decisive role in establishing the Mathematical Institute within the Czech Academy of Sciences and Arts and then in the early institutionalisation of mathematics under the Czechoslovak Academy (*Koutník, n.d.*; *Rákosník & Rozložník, 2021*). Through Čech, mathematical tradition and institutional construction became inseparable.

The significance of Čech's role lies not only in the fact that he founded an institute. It lies in the type of institute he helped imagine. Mathematics needed an institutional space different from both a university classroom and an applied technical laboratory. It required seminars, research time, graduate students, a library, journals, international exchange, and a culture of sustained abstraction. Čech understood that mathematical research could not flourish if it was reduced to teaching obligations or scattered among individuals without a common intellectual environment. The creation of the Mathematical Institute therefore represented a specific form of academic modernisation. It gave Czech mathematics a research institution capable of cultivating areas whose value might not be immediately visible to the state or to industry, but whose long-term importance for scientific culture was immense.

The early history of the Institute also shows how Czech mathematics was shaped by the broader European mathematical world. Čech's own work had international connections, including contacts with the Moscow school of topology and the Institute for Advanced Study in Princeton. This international dimension matters because it prevents a narrow national reading of mathematical tradition. Czech mathematics was national in its institutional mission, but international in its intellectual language. The Academy's mathematical institutes inherited this dual character. They helped create a Czech research environment while measuring themselves against universal standards of proof, originality, and communication. Mathematics was therefore one of the clearest fields in which national scientific ambition could be expressed without intellectual provincialism.

The institutionalisation of mathematics under the Czechoslovak Academy after 1953 brought both opportunities and constraints. On the one hand, the Academy offered stable positions, concentrated research capacity, graduate training, journals, and a clear place for mathematics within a state-supported research system. On the other hand, the socialist research order could impose ideological, administrative, and travel restrictions, and it shaped careers through political structures not always aligned with scientific merit. Mathematics was less ideologically exposed than history, sociology, law, or philosophy, but it was not outside politics. International contacts, appointments, access to literature, and participation in conferences could all be affected by the political climate. The discipline's relative abstraction protected it in some ways, but its institutional life still depended on the regime in which it was embedded.

The mathematical tradition of the Academy was shaped by several powerful figures whose work connected pure mathematics, applied analysis, numerical methods, and modern computation. The Institute of Mathematics itself identifies Eduard Čech, Jaroslav Kurzweil, Ivo Babuška, Jindřich Nečas, Miroslav Fiedler, and Vlastimil Pták among the distinguished personalities connected with its strongest traditions (*Rákosník & Rozložník, 2021*). This list is revealing because it includes not only pure topologists and analysts but also mathematicians whose work became foundational for numerical analysis, finite element methods, partial differential equations, graph theory, linear algebra, functional analysis, and computational science. Czech Academy mathematics therefore cannot be stereotyped as isolated pure abstraction. Its historical strength lay precisely in the movement between structural theory and mathematically rigorous approaches to problems arising from mechanics, physics, engineering, and computation.

Jaroslav Kurzweil represents one such line of continuity. His name is attached to the Henstock–Kurzweil integral and to important work in differential equations and stability theory. His career illustrates how Czech mathematical analysis could contribute to foundational questions while remaining close to problems of dynamical systems and mathematical modelling. The significance of the Kurzweil tradition lies in its refusal to divide mathematics too sharply into "pure" and "applied" domains. A new concept of integration may appear at first to belong to the inner logic of analysis, yet it can also influence differential equations, generalised solutions, and the mathematical treatment of systems not easily handled by classical frameworks. In this respect, Kurzweil's work exemplifies the Academy's broader mathematical culture: abstraction was valued not as escape from reality, but as a way of enlarging what could be treated rigorously (*Rákosník & Rozložník, 2021*).

Ivo Babuška represents another essential line: the emergence of computational and applied mathematics as a mathematically exact discipline. His work on the finite element method,

stability, error estimates, and the mathematical foundations of numerical computation placed Czech mathematics within one of the central developments of 20th-century applied analysis. The finite element method became indispensable for engineering, mechanics, physics, materials research, and simulation-based science. Babuška's importance therefore lies not only in his individual achievements but in the transformation of numerical methods into a rigorous mathematical field. The Academy tradition associated with Babuška shows that computation did not weaken mathematical standards; it created new demands for proof, convergence, stability, and reliability (*Rákosník & Rozložník, 2021*).

Jindřich Nečas gave the Academy another major tradition in partial differential equations, variational methods, and the mathematical theory of continuum mechanics. His work on elliptic equations, regularity of generalised solutions, and problems connected with elasticity and fluid mechanics helped shape Czech mathematical analysis in a direction where physical models were treated with great conceptual precision. This was institutionally significant because it linked the Institute of Mathematics with mechanics, thermodynamics, materials, and later numerical modelling. Nečas's legacy also helped create a bridge between the Academy and university mathematics, especially through seminars, students, and mathematical schools associated with Charles University and the broader Prague mathematical environment (*Rákosník & Rozložník, 2021*). Through this tradition, the Academy became a place where the mathematical foundations of physical processes could be explored without reducing them to engineering routine.

Miroslav Fiedler illustrates the Academy's contribution to linear algebra and graph theory. His name became associated with algebraic connectivity, the Fiedler vector, and spectral approaches to graphs. These concepts later acquired importance far beyond their original mathematical context, entering network theory, clustering, image segmentation, distributed systems, and computational analysis. The historical lesson is again non-linear. A result in matrix theory and graph theory may appear at the time as part of internal mathematical development, but later becomes indispensable in computational and data-oriented fields. Fiedler's career therefore shows how Academy mathematics could produce conceptual tools whose broader relevance became clearer only when new technological and scientific environments emerged (*Rákosník & Rozložník, 2021*).

Vlastimil Pták and the functional-analytic tradition added a further dimension. Functional analysis provided a language for operators, topological vector spaces, iterative methods, stability, and abstract structures underlying analysis and computation. Such work is often difficult to explain outside mathematics because its objects are highly abstract. Yet these abstractions may later become crucial for numerical algorithms, optimisation, quantum theory, control, and the theory of equations. Pták's tradition is therefore an example of the Academy's ability to maintain research that may not immediately present itself as publicly useful but forms part of the deep architecture of modern mathematical knowledge. This is one of the reasons why a public research institution is necessary: it can support intellectual work whose value unfolds across long timescales.

The Institute of Mathematics did not preserve these traditions by remaining unchanged. Its contemporary research profile includes mathematical analysis, differential equations, numerical analysis, functional analysis, theory of function spaces, mathematical logic, logical foundations of computer science, complexity theory, combinatorics, set theory, numerical linear algebra, topology, category theory, optimisation and control theory, algebraic and

differential geometry, and mathematical physics (*Rákosník & Rozložník, 2021*). This diversity shows that the institute is both historically rooted and dynamically adaptive. It contains older Czech strengths in topology, analysis, and numerical mathematics, but it also works in fields that have grown with theoretical computer science, mathematical physics, and data-oriented science. The continuity of the institute is therefore not the repetition of old topics, but the maintenance of a research culture capable of absorbing new questions.

The departmental structure described by the Institute reflects this combination of continuity and renewal. Abstract analysis continues older strengths in topology and functional analysis while moving towards descriptive set theory, algebraic topology, category theory, and C*-algebras. Algebra, geometry, and mathematical physics connect representation theory, algebraic geometry, homological algebra, string field theory, gravitation, and the Einstein equations. Evolution differential equations study multi-field processes in continuum mechanics, thermodynamics, fluids, solids, porous media, magnetohydrodynamics, liquid crystals, hysteresis, thermal effects, and phase transitions. Mathematical logic and theoretical computer science address proof complexity, bounded arithmetic, computational complexity, graph theory, set theory, and foundations. Numerical analysis continues traditions in finite element methods, numerical linear algebra, parallel computing, and computational fluid dynamics (*Rákosník & Rozložník, 2021*). This is not a small disciplinary remnant, but a broad mathematical ecosystem.

The Institute's role in mathematical publishing is another key element of institutional tradition. It publishes or supports journals that connect the present Academy to older Czech mathematical culture. The Czechoslovak Mathematical Journal and Mathematica Bohemica continue the tradition of Časopis pro pěstování mathematiky a fysiky, founded in 1872, while Applications of Mathematics specialises in work directed towards applications in science and technology (*Rákosník & Rozložník, 2021*). This publishing function is historically important because mathematical journals are not merely outlets for articles. They are institutions of memory, standards, and international communication. Through them, the Academy participates in the preservation and circulation of Czech mathematical production across generations.

The Institute's library and digital work further strengthen this memory-bearing role. The mathematical library has been described as the largest public mathematical library in the country, and the Czech Digital Mathematics Library was developed to digitise, organise, archive, and provide access to mathematical literature published in the Czech lands (*Rákosník & Rozložník, 2021*). This archival function is especially meaningful in mathematics because older results often remain alive longer than in many experimental sciences. A theorem from the 19th or early 20th century may still matter if it enters a new proof, model, or interpretation. By preserving mathematical literature, the Academy preserves not only historical documents but usable intellectual resources. The digital library also represents a modernisation of tradition: national mathematical memory becomes part of a wider digital and European knowledge environment.

The Institute of Mathematics is not the only Academy institution relevant to mathematical traditions. The Institute of Information Theory and Automation, established in 1959 by merging the Laboratory for Automation and Telemechanics with the Information Theory Department of the Institute of Radio Engineering and Electronics, became a major centre at the interface of mathematics, cybernetics, systems theory, control, information theory, signal processing, and

later artificial intelligence (*Institute of Information Theory and Automation, n.d.*). Its history shows how mathematics entered the Academy not only through pure analysis and topology but also through the language of information, control, and automation. This was especially important in the socialist period, when cybernetics and automation were linked to planning, industry, communications, defence, and the modernisation of technical systems. Yet UTIA's strongest work was not reducible to state planning. It produced internationally recognised results in information channels with memory, algebraic control theory, self-adjusting controllers, and modelling of large-scale gas distribution networks (*Institute of Information Theory and Automation, n.d.*).

UTIA's institutional identity also reveals the durable importance of interdisciplinary mathematics. The institute describes itself as conducting basic and applied research in artificial intelligence, signal and image processing, systems science, and selected parts of applied mathematics and computer science (*Institute of Information Theory and Automation, n.d.*). Its research areas include machine learning, natural language processing, knowledge representation, econometrics, computer vision, texture analysis, image restoration, blind deconvolution, superresolution, video tracking, complex adaptive systems, probability theory, applied statistics, data analysis, calculus of variations, optimisation theory, continuum mechanics, and econometrics (*Institute of Information Theory and Automation, n.d.*). Such a profile shows how the mathematical tradition of the Academy expanded into the computational and data-rich sciences without losing its theoretical core. In UTIA, mathematics is present as probability, optimisation, inference, modelling, control, and algorithmic structure.

The Institute of Computer Science of the Czech Academy of Sciences adds another layer to this institutional landscape. Its official history identifies its origins in 1975 as the main computing centre of the Czechoslovak Academy of Sciences, especially for scientists and numerical mathematicians, and notes its transformation into a scientific institute of the Czechoslovak Academy in 1980 (*Institute of Computer Science, n.d.*). This development is historically significant because it shows how computing first entered the Academy partly as infrastructure and then became a research field in its own right. The path from computing centre to research institute mirrors a broader global transformation: computers ceased to be merely calculating machines for other sciences and became objects of theoretical, methodological, and institutional inquiry. In the Czech Academy, this transformation connected numerical mathematics, algorithms, artificial intelligence, and the practical needs of research institutes.

The relationship between the Institute of Mathematics, UTIA, and the Institute of Computer Science demonstrates that mathematical tradition in the Academy is plural. It includes pure mathematics, applied mathematics, information theory, automation, numerical methods, theoretical computer science, artificial intelligence, and data-oriented modelling. These fields do not share a single method, but they share a concern with structure, inference, proof, optimisation, abstraction, and formalisation. The Academy's institutional arrangement allowed these traditions to develop in neighbouring but distinct spaces. This was important because mathematics and computation require both disciplinary depth and cross-disciplinary mobility. A theorem in logic may influence complexity theory; a numerical method may affect fluid mechanics; an optimisation principle may shape control; a probabilistic model may become central to machine learning.

The post-1989 transformation altered the conditions under which these mathematical institutes operated. They had to adapt to competitive funding, international evaluation, open recruitment, European collaboration, and new expectations of interdisciplinarity and public relevance. For the Institute of Mathematics, the 2007 transformation into a public research institution brought broader autonomy in research and personnel policy under public control (*Rákosník & Rozložník, 2021*). For UTIA, the same legal transformation brought greater autonomy in deciding research priorities and economic behaviour, together with greater responsibility for financial operations (*Institute of Information Theory and Automation, n.d.*). These reforms changed the administrative language of mathematical research, but they did not eliminate its long-term character. The challenge was to modernise governance without forcing mathematics into short-term utility.

The Academy's mathematical institutes also became important training environments. Although Academy institutes are not universities, they cooperate with universities in doctoral education, supervision, lectures, seminars, and research training. The Institute of Mathematics carries out doctoral study programmes in cooperation with universities and provides training for young scientists (*Rákosník & Rozložník, 2021*). UTIA similarly emphasises collaboration with universities at bachelor's, master's, and especially doctoral levels, where students remain affiliated with universities but receive supervision, dissertation topics, research support, and often financial support from the institute (*Institute of Information Theory and Automation, n.d.*). This model is essential for mathematical sciences because advanced research training cannot be separated from seminars, proof cultures, computational projects, and participation in research groups. The Academy thus helps reproduce mathematical elites while remaining distinct from the university system.

Internationalisation was another crucial dimension. The Institute of Mathematics reports a substantial presence of foreign researchers, postdoctoral fellows, international visitors, workshops, conferences, and the Eduard Čech Distinguished Visitor Programme, established in 2016 to attract distinguished mathematicians for extended collaboration (*Rákosník & Rozložník, 2021*). This international openness is especially important in mathematics, where the discipline is universal in language but often fragile in institutional scale. A strong institute in a medium-sized country must avoid isolation by maintaining seminars, visiting programmes, joint projects, and participation in European and global networks. Through such practices, the Academy's mathematical institutes remain connected to the international frontier while preserving Czech institutional continuity.

The Academy's mathematical traditions also have a public and cultural dimension. Mathematics is often less visible to the public than chemistry, astronomy, or medicine because its achievements are abstract and rarely appear as immediate products. Yet mathematical culture contributes to society by forming habits of precision, argument, modelling, and intellectual discipline. Public lectures, open days, digital libraries, popularisation projects, and cooperation with schools help make this culture visible. Čech's own interest in high-school mathematics and mathematical terminology already suggested that mathematical culture was not confined to research specialists alone (*Koutník, n.d.*). The modern Academy continues this wider educational responsibility through outreach and public communication. Such efforts are important because they defend the social legitimacy of abstract science.

The tradition of mathematics in the Czech Academy is therefore best understood as a form of intellectual infrastructure. It is less visible than a laser facility or a tokamak, but it underlies many of the same scientific capacities. Without mathematical analysis, numerical methods, optimisation, probability, logic, and computational theory, advanced physical modelling, data science, artificial intelligence, engineering simulation, systems control, and many areas of environmental and biological research would be much weaker. The Academy's mathematical institutes preserve this infrastructure not only by producing theorems but by maintaining seminars, journals, libraries, software competence, doctoral training, and international communities. They show that an academy's strength cannot be measured only by laboratories and instruments. It must also be measured by the depth of its abstract disciplines.

Thus, the mathematical institutes and traditions of the Czech Academy of Sciences reveal a long continuity from the post-war institutional work of Eduard Čech through the Czechoslovak Academy's schools of topology, analysis, numerical mathematics, control, and information theory to the contemporary world of theoretical computer science, artificial intelligence, data analysis, and mathematical modelling. This continuity was never static. It passed through Nazi occupation, socialist centralisation, normalisation, the Velvet Revolution, Czech statehood, public research reform, and European integration. The Academy preserved mathematics as an autonomous discipline while also enabling it to serve physics, engineering, informatics, biology, economics, and public knowledge. In this sense, mathematics within the Academy is not only a discipline of proofs; it is one of the quiet structures through which Czech science learned to think, model, compute, and remain intellectually connected to the world.

2. Theoretical Modelling, Computation, and Data Science

Theoretical modelling, computation, and data science changed the position of mathematics within the Czech Academy of Sciences by turning abstract reasoning into one of the central working instruments of contemporary research. Mathematics had always provided languages for physics, mechanics, astronomy, economics, and engineering, but the second half of the 20th century and the beginning of the 21st transformed this relationship. Models became more complex, computation became indispensable, and data became one of the primary materials of scientific work. The Academy's mathematical and computational institutes were therefore drawn into a new intellectual regime in which proof, algorithm, simulation, statistical inference, and empirical data increasingly had to work together. This did not abolish older mathematical traditions. On the contrary, it gave them new fields of application and new methodological urgency. Differential equations, optimisation, probability, numerical analysis, logic, control theory, machine learning, and statistical modelling became part of a common infrastructure through which the Academy studied natural, technical, biological, economic, and social systems (*Akademie věd České republiky, n.d.*; *Institute of Mathematics, n.d.*).

The development of theoretical modelling within the Academy cannot be separated from the older Czech traditions of analysis, partial differential equations, numerical mathematics, and mathematical physics. The Institute of Mathematics had long cultivated areas such as differential equations, numerical analysis, functional analysis, mathematical logic, numerical linear algebra, optimisation, control theory, and mathematical physics (*Institute of Mathematics, n.d.*). These fields formed the conceptual foundation for modelling long before "data science" became a common term. A model is not merely a simplified picture of reality; it is a disciplined mathematical construction that identifies variables, relations, constraints,

uncertainties, and possible dynamics. The Academy's modelling culture therefore emerged from a tradition in which mathematical abstraction was combined with attention to physical, mechanical, and computational problems. This tradition made it possible for Czech mathematics to participate in the later rise of simulation-based science.

Theoretical modelling also changed the meaning of experimentation. In older scientific cultures, theory and experiment could often be imagined as separate domains: theory formulated laws, and experiment tested them. In contemporary research, especially in fields studied by the Academy, this separation became less stable. Models can generate hypotheses, guide experiments, reconstruct inaccessible processes, interpret large datasets, and estimate quantities that cannot be measured directly. A climate model, a plasma simulation, a material model, a biological network, or an economic model is not an experiment in the classical laboratory sense, but it functions as a disciplined exploratory environment. The Academy's mathematical institutes became important because they could provide the methods needed to build such environments responsibly. Without mathematical control, computational models risk becoming visually impressive but scientifically unstable.

The numerical solution of differential equations is one of the clearest examples of this transformation. Many processes studied by the natural and technical sciences are described through differential equations: fluid flow, elasticity, heat transfer, electromagnetic fields, chemical reactions, population dynamics, phase transitions, and wave propagation. Yet exact solutions are rare, especially when real geometry, nonlinear behaviour, multiple scales, or boundary conditions are involved. Numerical methods therefore become the bridge between theory and usable knowledge. The Academy's traditions in finite element methods, numerical linear algebra, error estimates, and computational mechanics allowed mathematical theory to enter practical modelling without losing rigour. The work associated with Ivo Babuška and later Czech numerical analysts showed that computation itself requires mathematical proof, not only programming skill (*Rákosník & Rozložník, 2021*).

This insistence on rigour is historically important. Computation can create an illusion of certainty because numbers, images, and simulations appear precise. Yet numerical results can be misleading if algorithms are unstable, meshes are inadequate, convergence is not understood, or uncertainty is ignored. The Academy's mathematical culture helped defend a more mature view: computation is a form of reasoning only when its limits are examined. Numerical analysis, error control, stability theory, and verification are therefore not technical details but epistemological safeguards. They determine whether a simulation can be trusted. This made the Academy's mathematical institutes essential not only for solving equations but for defining standards of reliability in model-based science.

The Institute of Mathematics contributed to this culture through departments concerned with evolution differential equations, constructive methods of mathematical analysis, numerical analysis, optimisation, control theory, mathematical physics, and related areas (*Institute of Mathematics, n.d.*). These fields are not isolated specialisms. They form a methodological continuum from abstract existence theorems to computational algorithms, from functional spaces to finite elements, and from mathematical physics to simulation of continuum processes. In this continuum, the Academy's role was to preserve depth. It could sustain researchers who worked on foundational questions of analysis while also supporting methods that entered mechanics, thermodynamics, materials science, and engineering. The value of

such work often becomes apparent only over time, when a mathematically secure method proves capable of supporting new scientific or technological domains.

The Institute of Computer Science added another institutional layer to this development. Its origins as the main computing centre of the Czechoslovak Academy of Sciences in the 1970s and its later transformation into a scientific institute illustrate the changing status of computation itself (*Institute of Computer Science, n.d.*). At first, computing served other sciences by providing calculation capacity to researchers who needed numerical support. Gradually, however, computer science became an independent research field concerned with algorithms, complexity, artificial intelligence, machine learning, statistical modelling, complex systems, and the theory and application of computing. This transformation is central to the Academy's modern history. It shows how an infrastructure created to support calculation became a source of theoretical and methodological innovation.

The Institute of Computer Science describes its fundamental research as focused on theoretical computer science and artificial intelligence, with the aim of frontier research and participation in the identification of new trends and directions in basic research (*Institute of Computer Science, n.d.*). This formulation is significant because it places computation within the Academy's basic-science mission rather than treating it only as technical service. Algorithms, complexity theory, formal methods, machine learning, and artificial intelligence are not merely tools borrowed from elsewhere. They are scientific objects in their own right. The Academy's role is to study their foundations, limits, and applications while keeping them connected to broader scientific and social questions. In this respect, computer science became one of the heirs of mathematical reasoning in the digital age.

Artificial intelligence represents the most visible contemporary expression of this shift. Within the Academy, AI developed not as a sudden fashion but through older traditions of machine learning, neural networks, statistical learning, optimisation, knowledge representation, automated reasoning, pattern recognition, signal processing, and complex systems. The Institute of Computer Science conducts research on the theoretical foundations of machine learning algorithms and biologically inspired optimisation methods, as well as applications involving data separation and time-series prediction in science, engineering, and other social fields (*Institute of Computer Science, n.d.*). This description is important because it reveals an approach to AI grounded in mathematics and modelling, not only in software implementation. AI in the Academy is therefore connected to the question of how machines can infer, classify, predict, optimise, and reason under uncertainty.

The Institute of Information Theory and Automation represents another major institutional centre for modelling, computation, and data science. Founded in 1959, it grew out of the cybernetic, information-theoretical, and automation traditions of the Czechoslovak Academy and later developed into a public research institute focused on artificial intelligence, signal and image processing, systems science, and applied mathematics (*Institute of Information Theory and Automation, n.d.*). Its history is especially revealing because it connects the early post-war and socialist fascination with cybernetics and automation to contemporary AI and data-driven science. What once appeared under the language of telemechanics, control, information channels, and systems theory later reappeared in the language of machine learning, probabilistic modelling, computer vision, natural language processing, econometrics, and complex adaptive systems.

UTIA's contemporary research profile shows how data science emerges from several older mathematical traditions. Artificial intelligence at the institute includes machine learning, natural language processing, knowledge representation, econometrics, and computer vision. Signal and image processing includes image restoration, blind deconvolution, superresolution, texture analysis, video tracking, recognition, and related areas. Systems science includes decision-making, adaptive systems, probability theory, statistics, data analysis, optimisation, continuum mechanics, and econometrics (*Institute of Information Theory and Automation, n.d.*). This is not a random accumulation of modern keywords. It is a coherent development from information, uncertainty, control, and modelling towards the analysis of complex data-rich systems. UTIA therefore demonstrates that data science in the Academy did not begin from the commercial rhetoric of "big data"; it grew from rigorous traditions of information theory, statistics, systems science, and applied mathematics.

The importance of uncertainty is central here. Real data are incomplete, noisy, biased, indirect, and often structured by measurement systems that introduce their own assumptions. A serious data science must therefore be probabilistic, statistical, and model-aware. The Academy's traditions in information theory, Bayesian modelling, decision theory, and statistical inference are crucial because they prevent data from being treated as self-explanatory. Data do not speak by themselves. They require models of generation, representation, error, uncertainty, dependence, causality, and interpretation. UTIA's work in probabilistic methods, Bayesian networks, uncertainty processing, and decision-making theory reflects this deeper understanding of data science as a discipline of disciplined inference rather than mere accumulation of information (*Institute of Information Theory and Automation, n.d.*).

The rise of data science also changed the relationship between mathematics and empirical fields. In earlier periods, mathematical modelling was often associated with physics, mechanics, engineering, and economics. Today it also enters biology, medicine, neuroscience, environmental science, linguistics, social sciences, humanities, and cultural heritage research. Image processing can support medicine and astronomy; machine learning can support materials discovery or climate analysis; statistical models can be used in economics and epidemiology; network analysis can illuminate social systems or biological pathways; optimisation can improve logistics, energy systems, or experimental design. The Academy's computational institutes are well positioned for this transformation because they are embedded in a multi-disciplinary research organisation. They can collaborate across institutes more naturally than a narrowly departmental university unit might.

Theoretical modelling also acquired a new role in physical research. Plasma physics, high-energy experiments, laser–matter interaction, materials science, nuclear physics, and astrophysics all depend increasingly on simulation, data analysis, and computational inference. Models are needed to interpret detector outputs, simulate particle interactions, predict plasma behaviour, reconstruct images, analyse spectra, and compare experimental results with theory. The connection between the Academy's physical institutes and its mathematical-computational institutes is therefore structurally important. The study of matter has become inseparable from the modelling of matter. Computation does not replace the laboratory, but the laboratory increasingly depends on computation to make its results intelligible.

In chemistry and materials science, the same movement is visible. Molecular modelling, quantum chemistry, reaction modelling, catalysis simulation, polymer dynamics, materials informatics, and machine-learning-assisted design all connect chemical intuition with computational methods. These developments make mathematics and computer science part of the creative process of chemistry. A molecule or material may be proposed, screened, optimised, or interpreted through computation before or after synthesis. The Academy's multi-institute structure makes this form of interaction especially valuable. The chemical institutes bring experimental knowledge and molecular problems; mathematical and computational institutes bring algorithms, models, statistical frameworks, and numerical methods. Their cooperation reflects a broader transformation of modern science from disciplinary separation to method-based integration.

Data science also affected the life sciences within the Academy. Biological and medical research increasingly produces large and complex datasets: genomic sequences, proteomic profiles, microscopy images, behavioural data, physiological signals, ecological observations, and clinical measurements. Such data require statistical modelling, machine learning, image analysis, network inference, and computational pipelines. The Academy's expertise in AI, signal processing, probabilistic modelling, and complex systems can therefore support biological interpretation. This does not mean that mathematics replaces biological expertise. Rather, it allows biological questions to be asked at new scales and levels of complexity. The result is a new partnership between experimental life science and formal reasoning.

The growth of computational modelling also transformed engineering and technical sciences. Mechanics, thermomechanics, fluid dynamics, control systems, robotics, power systems, transport, and industrial processes all depend on simulations and optimisation. Academy institutes concerned with mechanics and thermomechanics require mathematical models of continuum behaviour, heat and mass transfer, turbulence, structural stability, vibration, and coupled processes. These models are not merely calculations after the fact; they can guide experiments, reduce risk, improve design, and identify hidden mechanisms. The mathematical traditions of partial differential equations, numerical analysis, and optimisation therefore support technological sciences across the Academy. They give engineering research analytical depth and predictive capacity.

Theoretical modelling in the Academy also became important for economics and social systems. UTIA's work includes econometrics, decision-making, adaptive systems, and complex systems, which allow formal analysis of markets, uncertainty, policy effects, and networked behaviour (*Institute of Information Theory and Automation, n.d.*). This is significant within the broader history of the Academy because it connects mathematical methods to domains that had been ideologically sensitive under state socialism. After 1989, economic modelling, statistical inference, and decision theory could be re-situated within a more open research environment. The Academy's mathematical-computational capacities therefore contributed to the reconstruction of analytical social science as well as to natural and technical fields.

The growth of computation also required new institutional habits. Mathematical research can be conducted with paper, boards, and seminars, but computational research requires hardware, software, data storage, programming skills, reproducibility standards, cybersecurity, version control, and long-term maintenance of code and datasets. The Institute of Computer Science's origin in computing infrastructure gave the Academy a historical

advantage in understanding this material side of computation. Yet the contemporary situation is more demanding. Data-intensive research requires not only access to machines but also expertise in data governance, algorithmic transparency, and reproducible workflows. The Academy's computational institutes therefore became part of the institutional infrastructure of scientific reliability.

Algorithmic modelling also raises questions of explainability and trust. A mathematical proof can be checked through formal reasoning; a numerical model can be tested through convergence and validation; a machine-learning model may produce accurate predictions while remaining difficult to interpret. This creates a new epistemological challenge for the Academy. If AI is to be used in science, medicine, public policy, or industrial systems, researchers must understand not only its performance but also its assumptions, biases, robustness, and limits. The Academy's traditions in theory, statistics, logic, and mathematical modelling are especially important here. They can help prevent AI from becoming a black-box technology detached from scientific accountability.

The Academy's Strategy AV21 programme "Artificial Intelligence for Science and Society" reflects this new institutional awareness. Coordinated by the Institute of Computer Science, the programme aims to advance high-quality research in selected disciplines of artificial intelligence and machine learning, foster the application of AI and machine-learning methods across scientific disciplines, coordinate AI-related activities across Academy institutes, and strengthen cooperation among them (*Institute of Computer Science, n.d.*). This programme is historically significant because it makes AI not only a specialised research field but a cross-Academy methodological priority. It acknowledges that AI has become a general technology of knowledge production, capable of affecting physics, chemistry, biology, humanities, social science, and public administration. At the same time, by situating AI within the Academy, it reinforces the need for scientific responsibility rather than purely commercial enthusiasm.

The rise of data science also transformed the public mission of the Academy. In contemporary societies, decisions about health, climate, energy, transport, security, education, economy, and public administration increasingly rely on models and data. A public research institution must therefore be capable of evaluating, building, and criticising such models. The Academy's mathematical and computational institutes can provide independent expertise in areas where commercial or political actors may have strong interests. This is part of scientific autonomy in the digital age. Autonomy no longer means only freedom from ideological interference; it also means the capacity to assess models, algorithms, and data claims without subordination to market or governmental convenience.

This public role is visible in fields such as image analysis and signal processing. UTIA researchers work on restoration, deconvolution, superresolution, recognition, and pattern analysis, methods that may enter medicine, security, robotics, remote sensing, astronomy, and cultural heritage. These methods affect how society sees and interprets images. In an era of synthetic media, manipulated photographs, and AI-generated content, expertise in image processing also acquires civic relevance. The Academy's work in this area therefore belongs both to technical science and to the broader problem of trustworthy visual evidence. This illustrates a general principle: computational methods become socially important when they mediate between raw data and human judgement.

The mathematical-computational turn also affected the notion of interdisciplinarity. In earlier institutional language, interdisciplinarity often meant cooperation between neighbouring

fields, such as physics and chemistry or biology and medicine. Computation and data science changed this pattern because they offer methods that can travel across very different objects. The same statistical idea may be used in climate modelling, neuroscience, economics, and materials science; the same optimisation method may support engineering design, machine learning, and resource allocation; the same graph-theoretical concept may enter network biology, social analysis, and computer science. The Academy's computational institutes therefore became methodological connectors across the whole institution. Their importance cannot be measured only by their own disciplinary outputs, because they also shape the research capacity of other fields.

At the same time, interdisciplinarity creates risks. When mathematical and computational methods travel too quickly, they may be used superficially by researchers who do not understand their assumptions. Machine learning may be applied to inadequate data; statistical correlations may be mistaken for causation; simulations may be trusted beyond their validation range; optimisation may ignore ethical or social constraints. The Academy's role is not only to promote modelling and data science, but to cultivate their responsible use. This requires collaboration in which domain experts and method experts treat one another as intellectual partners. The best interdisciplinary work is not the export of algorithms into passive fields, but the joint construction of questions, models, and interpretations.

The relationship between computation and human expertise is therefore central. Data science does not eliminate the need for scientists who understand physical processes, chemical mechanisms, biological systems, historical sources, or social institutions. Rather, it changes the form of expertise. A climate scientist, chemist, physicist, or historian may need to work with data analysts, statisticians, and machine-learning researchers, while the latter must understand enough of the domain to avoid formal emptiness. The Academy's multi-institute environment can support this mutual learning because it brings diverse research cultures into one public organisation. This institutional proximity is one of its advantages over more fragmented research systems.

The growth of computation also affects scientific careers. Younger researchers increasingly need hybrid skills: mathematical literacy, programming, data handling, statistical thinking, disciplinary knowledge, and communication across fields. The Academy's institutes contribute to this training through doctoral supervision, seminars, joint programmes, workshops, and collaboration with universities. The Machine Learning and Modelling Seminar organised jointly by the Institute of Computer Science and the Faculty of Mathematics and Physics of Charles University is one example of how Academy and university environments intersect around contemporary computational research (*Institute of Computer Science, n.d.*). Such seminars are not merely academic events; they are mechanisms through which new research communities are formed and maintained.

The Academy's computational and mathematical institutes also help connect Czech science to international research networks. Modelling, AI, machine learning, and data science are global fields with rapidly changing standards, open-source communities, international conferences, and strong competition for talent. A national institute can remain relevant only if it participates in these networks while maintaining a clear research identity. The Czech Academy's advantage lies in its combination of older mathematical depth and newer computational orientation. This combination allows it to contribute not only applications of imported methods but also theoretical and methodological development. International

visibility in these areas is essential because computational science evolves through shared benchmarks, publications, datasets, software, and conferences.

The historical transformation from mathematical modelling to data science also changes how the Academy's past should be interpreted. Earlier work in topology, functional analysis, numerical methods, information theory, control, and automation may seem distant from contemporary AI. Yet many of the conceptual foundations are connected. Machine learning relies on optimisation, statistics, function approximation, geometry, probability, and computational complexity. Data science relies on inference, linear algebra, graph theory, numerical stability, and algorithmic thinking. Systems science relies on control, feedback, adaptation, and decision theory. The Academy's contemporary computational culture is therefore not a rupture with its mathematical traditions. It is one of their major continuations.

This continuity matters because it protects the Academy from purely fashionable readings of digital transformation. AI and data science are often presented as abrupt technological revolutions detached from older intellectual histories. The Academy's experience suggests a more sober interpretation. Contemporary AI is new in scale, speed, and public visibility, but it grows from long histories of mathematics, statistics, cybernetics, computation, modelling, and automation. By placing AI within this longer history, the Academy can treat it critically and constructively. It can recognise its transformative potential while resisting exaggerated promises and simplistic narratives. This historical depth is one of the Academy's intellectual assets.

Thus, theoretical modelling, computation, and data science became a central bridge between the Academy's mathematical traditions and the demands of contemporary science. Through the Institute of Mathematics, the Institute of Computer Science, and the Institute of Information Theory and Automation, the Czech Academy developed capacities in differential equations, numerical methods, optimisation, control, artificial intelligence, machine learning, signal and image processing, statistics, information theory, complex systems, and data analysis. These capacities support physics, chemistry, biology, engineering, economics, environmental research, and public expertise. They also show that the Academy's modernisation was not only a matter of new buildings or international memberships, but of new epistemic instruments. In the digital age, the Academy's ability to model, compute, infer, and interpret data became one of the key conditions of its scientific autonomy and public relevance.

3. The Growth of Computational and Interdisciplinary Methods

The growth of computational and interdisciplinary methods within the Czech Academy of Sciences represents one of the most important transformations of the late 20th and early 21st centuries. It changed not only the techniques used by researchers, but also the way scientific problems were formulated, organised, and justified. Computation became a common language across physics, chemistry, biology, environmental science, engineering, economics, linguistics, cultural heritage studies, and the social sciences. Interdisciplinarity, in turn, ceased to mean only occasional cooperation between neighbouring disciplines and became a structural condition of advanced research. Within the Academy, this transformation was supported by older traditions in mathematics, cybernetics, numerical analysis, information theory, automation, and computer science. The result was not the replacement of disciplinary

knowledge by algorithms, but the emergence of new forms of research in which mathematical models, computational tools, empirical data, and domain expertise became inseparable (*Akademie věd České republiky, n.d.*; *Institute of Computer Science, n.d.*).

This development had deep institutional roots. The Academy's mathematical institutes had long cultivated differential equations, numerical analysis, functional analysis, optimisation, control theory, mathematical logic, and theoretical computer science. The Institute of Information Theory and Automation grew from the Czechoslovak tradition of cybernetics, information theory, control, and systems science. The Institute of Computer Science emerged from the General Computing Centre of the Czechoslovak Academy of Sciences and gradually became a research institute focused on computing, artificial intelligence, theoretical computer science, and related methods (*Institute of Computer Science, n.d.*; *Institute of Information Theory and Automation, n.d.*; *Rákosník & Rozložník, 2021*). These histories matter because they show that computational interdisciplinarity in the Academy did not appear suddenly with the recent popularity of artificial intelligence. It developed through decades of work on models, algorithms, signals, systems, and numerical methods.

In the Czechoslovak period, computation first entered many institutes as a tool of calculation. Physicists needed numerical solutions of equations, engineers needed simulations, economists needed quantitative models, and chemists needed increasingly complex calculations of molecular and process behaviour. At this stage, computing was often treated as infrastructure rather than as an autonomous research culture. Yet even then, the use of computers changed scientific habits. It made larger systems mathematically tractable, encouraged new kinds of approximation, and created demand for specialists who could translate scientific problems into formal and computational procedures. The Academy's computing centres and mathematical institutes therefore helped prepare the ground for a later transformation in which computation would become not merely an auxiliary technique, but a way of producing knowledge.

The post-1989 transformation accelerated this process. The opening of Czech science to international networks, European projects, competitive funding, and new technologies placed greater emphasis on modelling, data processing, software, and interdisciplinary cooperation. Academy institutes had to publish internationally, join collaborative projects, modernise equipment, and respond to research questions that no single discipline could solve alone. Climate change, energy systems, biomedical research, nanomaterials, plasma physics, cultural heritage protection, disinformation, environmental monitoring, and artificial intelligence all required combinations of methods. Computation became one of the main means by which such combinations could be organised. It allowed researchers from different domains to work with shared models, datasets, simulations, and visualisations, even when their disciplinary languages differed.

The Institute of Mathematics remained central to this transformation because many computational methods depend on mathematical depth. Numerical analysis, optimisation, partial differential equations, mathematical logic, complexity theory, numerical linear algebra, topology, and control theory provide the foundations on which reliable computational research rests (*Institute of Mathematics, n.d.*). Without these foundations, computation risks becoming a collection of procedures whose accuracy, stability, and meaning are uncertain. The Academy's mathematical traditions therefore acted as a safeguard against superficial digitalisation. They ensured that computational methods remained connected to proof,

convergence, structure, and conceptual clarity. This was especially important as simulations and data-driven models became more visually persuasive and socially influential.

The growth of computational methods also gave new relevance to older Czech strengths in applied analysis and numerical mathematics. Problems in continuum mechanics, thermodynamics, fluid dynamics, elasticity, electromagnetic fields, phase transitions, and material behaviour require equations that often cannot be solved analytically. Numerical methods allow such systems to be studied, but only if the methods are mathematically justified. The Academy's work in finite element methods, numerical linear algebra, constructive analysis, and evolution differential equations helped connect mathematical theory with physical and engineering problems. This continuity shows that the digital turn did not make classical mathematical analysis obsolete. It made its rigour more necessary, because computation expanded the scale and ambition of modelling.

The Institute of Computer Science gave the Academy a different but complementary capacity. Its origins in the Academy's computing infrastructure placed it at the intersection of service and science, but its later development transformed it into a centre for theoretical computer science, artificial intelligence, machine learning, and computing for science and society (*Institute of Computer Science, n.d.*). This institutional path illustrates a broader global movement. Computing first supported research by providing calculation, then became a field that generated its own theories, and finally became a methodological environment for many other sciences. The Academy's Institute of Computer Science therefore became both a specialist institute and a cross-disciplinary partner. Its work helped shape the computational conditions under which other Academy fields could develop.

Artificial intelligence intensified this cross-disciplinary role. The Institute of Computer Science emphasises research in the theoretical foundations of machine learning and biologically inspired optimisation methods, as well as applications involving data separation, prediction, and modelling in different scientific and social domains (*Institute of Computer Science, n.d.*). AI is often publicly discussed as a technology of automation, but within the Academy it is better understood as a family of mathematical and computational methods for inference, classification, prediction, representation, and decision-making under uncertainty. Its importance lies not only in making machines perform tasks, but in changing how researchers handle complexity. Machine learning can detect patterns in large datasets, support hypothesis generation, assist image and signal interpretation, and accelerate modelling in fields from materials science to biology. Yet its responsible use requires mathematical understanding and domain expertise.

The Strategy AV21 programme "Artificial Intelligence for Science and Society" made this development explicit at the level of the whole Academy. Coordinated by the Institute of Computer Science, the programme aims to advance research in artificial intelligence and machine learning, foster AI and machine-learning applications across scientific disciplines, coordinate AI-related activities among Academy institutes, and strengthen cooperation within the institution (*Institute of Computer Science, n.d.*). This is institutionally significant because it treats AI not as a fashionable isolated topic, but as a methodological challenge for the entire Academy. The programme acknowledges that AI can support chemistry, physics, biology, environmental science, humanities, and social research, but it also implies that such support must be coordinated, critically assessed, and scientifically grounded. The Academy thereby

attempts to place AI within public research responsibility rather than within technological enthusiasm alone.

The Institute of Information Theory and Automation represents another major route through which computational interdisciplinarity developed. Its contemporary research profile includes artificial intelligence, signal and image processing, systems science, and applied mathematics (*Institute of Information Theory and Automation, n.d.*). Each of these areas is intrinsically interdisciplinary. Signal processing can serve medicine, astronomy, remote sensing, robotics, audio analysis, and cultural heritage research. Systems science can be applied to control, economics, energy systems, ecology, engineering, and decision-making. Applied mathematics can support probability theory, statistics, optimisation, continuum mechanics, and econometrics. UTIA therefore functions as one of the Academy's key methodological bridges between formal disciplines and empirical fields.

The history of UTIA also shows how older cybernetic and information-theoretical traditions were transformed rather than discarded. In the socialist period, cybernetics and automation were connected to industrial modernisation, control systems, telecommunications, and state planning. Some of these associations were politically conditioned, but the mathematical and technical content of systems theory, control, feedback, information channels, signal processing, and decision-making remained scientifically productive. After 1989, these traditions could be reinterpreted within a more open international environment. They became foundations for machine learning, computer vision, probabilistic modelling, adaptive systems, and data analysis. This continuity reveals one of the recurring patterns of the Academy's history: institutional and political contexts change, but methods can survive by moving into new scientific languages.

Signal and image processing provide one of the clearest examples of computational interdisciplinarity. Images are central to contemporary science, whether they come from microscopes, telescopes, satellites, medical scanners, historical paintings, industrial cameras, or experimental detectors. Yet images are not transparent windows onto reality. They are shaped by noise, blur, resolution limits, illumination, sensor properties, reconstruction algorithms, and interpretation. Research in image restoration, superresolution, deconvolution, recognition, texture analysis, and computer vision therefore becomes a form of scientific mediation. The Academy's expertise in this field allows researchers to recover, clarify, compare, and interpret visual information in ways that can affect medicine, cultural heritage, robotics, materials science, and environmental observation (*Institute of Information Theory and Automation, n.d.*).

The cultural heritage dimension of computational methods is especially revealing. At first glance, image processing and artificial intelligence may appear far removed from the traditional mission of humanities institutes or heritage research. Yet computational analysis can help detect underdrawings in paintings, compare visual patterns, preserve digital records, analyse degraded materials, and support documentation of fragile cultural artefacts. Such work shows that interdisciplinarity is not limited to natural and technical sciences. It can connect mathematics, computer vision, art history, conservation science, chemistry, and archival practice. In the Academy, where humanities and natural sciences coexist within one institution, such crossings are more than occasional curiosities. They demonstrate the institutional value of housing diverse research cultures under a common public framework.

The growth of data science further broadened this pattern. Data science depends on statistics, probability, optimisation, machine learning, databases, visualisation, and domain interpretation. It is often described as a new field, but within the Academy it grew from long-standing traditions in applied mathematics, information theory, econometrics, systems science, and computer science. UTIA's applied mathematics includes probability theory, applied statistics, data analysis, calculus of variations, optimisation theory, continuum mechanics, and econometrics (*Institute of Information Theory and Automation, n.d.*). This background gives data science conceptual discipline. It reminds researchers that data are not neutral accumulations of facts but structured outputs of measurement, classification, modelling, and social or natural processes.

The distinction between data and evidence is crucial. A dataset may be large without being reliable, representative, or meaningful. Computational methods can reveal patterns, but patterns may reflect measurement bias, sampling error, hidden confounders, or artefacts of preprocessing. The Academy's mathematical and statistical expertise is therefore essential for responsible interdisciplinary research. It helps researchers ask what a model assumes, how uncertainty is represented, whether conclusions are robust, and where interpretation exceeds evidence. This is particularly important in areas with public consequences, such as health, environmental risk, climate adaptation, economic policy, artificial intelligence, and disinformation. The Academy's contribution is not simply to process data faster, but to make data-based reasoning more trustworthy.

The study of disinformation illustrates this public dimension of computational methods. The Institute of Computer Science lists research related to the creation, dissemination, reception, and impact of disinformation, including the use of artificial intelligence tools in its detection (*Institute of Computer Science, n.d.*). Such work connects computer science with sociology, media studies, political communication, linguistics, statistics, and ethics. It also shows how computational methods enter the democratic public sphere. Algorithms can detect suspicious patterns, but they must be interpreted in relation to human communication, social trust, political context, and freedom of expression. This is a typical interdisciplinary problem: neither technical analysis nor social theory alone is sufficient. The Academy's public research mission gives it a suitable framework for such work because it can combine methodological expertise with civic responsibility.

In the natural sciences, computational methods transformed chemistry and materials research. Molecular modelling, quantum chemistry, polymer simulations, catalysis modelling, materials informatics, and machine-learning-guided design changed how chemists think about substances before and after synthesis. A material can be modelled at several scales: electronic structure, molecular arrangement, mesoscale morphology, macroscopic behaviour, and device performance. This multi-scale thinking requires cooperation among chemists, physicists, mathematicians, and computer scientists. The Academy's chemical and physical institutes, supported by mathematical-computational expertise, are well positioned for such work. Computational interdisciplinarity allows chemistry to move from empirical synthesis alone towards prediction, screening, optimisation, and mechanism-based design.

In physics, computation became indispensable across almost every advanced field. Plasma confinement, laser–matter interaction, condensed matter systems, detector data, nuclear reactions, astrophysical signals, and materials under extreme conditions all require modelling and data analysis. Large experimental infrastructures produce volumes of data that cannot be

interpreted without algorithms. Simulations help design experiments, estimate parameters, test theoretical scenarios, and compare observations with models. The Academy's physical institutes therefore depend increasingly on mathematical and computational methods, while mathematical institutes gain new problems from physical research. This reciprocal movement is one of the defining features of modern scientific interdisciplinarity.

Environmental and Earth sciences also rely heavily on computational methods. Climate research, atmospheric modelling, hydrology, geophysics, landscape change, biodiversity assessment, and environmental monitoring all require data assimilation, time-series analysis, spatial modelling, uncertainty quantification, and simulation. These problems are inherently interdisciplinary because they combine physical processes, biological systems, human activity, and long-term observation. The Academy's computational capacities can support this research by providing statistical and modelling methods, while environmental institutes supply observational data and domain knowledge. Here again, computation becomes a language through which different fields cooperate without losing their specific expertise.

Biology and biomedical research changed perhaps most dramatically under the pressure of data-intensive methods. Genomics, proteomics, high-resolution microscopy, electrophysiology, epidemiological data, and biomedical imaging all produce complex information that cannot be interpreted by traditional laboratory intuition alone. Machine learning, statistical modelling, image analysis, network inference, and bioinformatics become necessary partners of experiment. The Academy's interdisciplinary environment allows computational researchers to work with life scientists on questions of classification, prediction, mechanism, and diagnosis. This does not mean that biological judgement is replaced by algorithms. Rather, algorithms expand the scale at which biological questions can be asked and help identify patterns that require further experimental interpretation.

The engineering sciences within the Academy also benefited from this methodological growth. Mechanics, thermomechanics, control, robotics, materials engineering, transport, energy systems, and industrial processes are all increasingly simulation-driven. Computational models can reduce experimental costs, anticipate failure modes, optimise design, and improve safety. Systems theory and control methods are particularly important where machines, processes, and environments interact dynamically. The Academy's traditions in automation, control, optimisation, and continuum mechanics provide a strong basis for this type of research. They also show that interdisciplinarity is often a matter of method moving across different physical and technological systems.

The social sciences and economics were also affected by the computational turn. Econometrics, decision theory, network analysis, agent-based modelling, text analysis, and statistical inference allow researchers to study markets, organisations, public behaviour, policy effects, and social communication in new ways. The Academy's institutes in information theory, automation, and computer science provide methods that can support such research, but the interpretation of social data requires strong domain knowledge and ethical caution. Social systems cannot be treated simply as mechanical systems with more variables. Computational methods can clarify patterns, but they can also conceal assumptions about human behaviour. The Academy's interdisciplinary work must therefore remain sensitive to the difference between modelling natural processes and modelling social life.

The humanities increasingly encountered computational methods as well. Digital humanities, corpus linguistics, historical databases, stylometry, network analysis of correspondence,

spatial humanities, and image-based analysis of manuscripts or artworks all require computational tools. In an academy that contains both exact sciences and humanities, these possibilities are institutionally meaningful. They allow older archival and interpretative traditions to meet newer methods of pattern recognition and data organisation. Yet the best digital humanities work does not abandon close reading, historical context, or philological precision. It uses computation to extend questions, not to flatten them. This principle reflects a broader Academy ideal: interdisciplinary methods should enrich disciplines rather than dissolve them.

The growth of computational methods also changed the meaning of infrastructure. In the physical sciences, infrastructure often means instruments, laboratories, and large devices. In computational and interdisciplinary research, infrastructure also means software, datasets, code repositories, algorithms, standards, metadata, digital libraries, and trained personnel. These infrastructures are less visible than lasers or accelerators, but they are equally important. They determine whether results can be reproduced, reused, verified, and connected across projects. The Academy's mathematical and computational institutes therefore contribute to infrastructure not only by maintaining hardware or services, but by creating methodological reliability.

Reproducibility became one of the central challenges of computational science. A published result based on code, data, and modelling assumptions may be difficult to verify unless the workflow is documented and accessible. This issue is not limited to computer science; it affects biology, climate research, economics, image processing, materials science, and any field using complex computational pipelines. The Academy's public research mission requires attention to reproducibility, transparency, and methodological accountability. Interdisciplinary work increases this responsibility because collaborators from different fields must understand enough of one another's methods to trust the results. Computation therefore forces a new discipline of documentation and communication.

The rise of artificial intelligence also raised ethical and epistemological questions. AI systems can classify, predict, generate text or images, detect anomalies, and optimise decisions, but they can also reproduce biases, obscure reasoning, and produce persuasive errors. The Academy's traditions in logic, probability, statistics, explainable machine learning, and systems theory are important because they support critical engagement with AI rather than passive adoption. The Institute of Computer Science identifies competencies in symbolic and explainable machine learning, where algorithms are designed to provide understandable rules and transparent explanations for classification decisions (*Institute of Computer Science, n.d.*). Such work is especially important in domains where trust, accountability, and human decision-making cannot be delegated blindly to opaque systems.

Interdisciplinary computational methods also created new forms of collaboration between Academy institutes and universities. Seminars, doctoral supervision, joint projects, shared software, methodological workshops, and research programmes became mechanisms through which mathematical and computational expertise circulated. The Machine Learning and Modelling Seminar, organised jointly by Charles University and the Institute of Computer Science, is one example of this cooperation (*Institute of Computer Science, n.d.*). Such activities are not peripheral to institutional history. They show how new research communities are built, how young researchers acquire hybrid skills, and how the Academy's non-university research environment complements university education.

Career structures changed accordingly. A young researcher in the Academy might now need to understand a disciplinary object and also work with code, statistics, data formats, visualisation, machine learning, or modelling assumptions. Conversely, a mathematician or computer scientist increasingly needs to communicate with chemists, biologists, physicists, economists, historians, or engineers. This creates both opportunity and pressure. Hybrid researchers can move across fields and ask new questions, but they may also face evaluation systems that remain disciplinary. The Academy's challenge is to recognise and reward interdisciplinary work without losing the standards of expertise that make such work credible.

The growth of computational interdisciplinarity also reshaped institutional governance. Programmes like Strategy AV21 require coordination across institutes, shared priorities, and the ability to identify public challenges that demand multiple forms of expertise. AI, climate, energy, health, security, and cultural heritage cannot be assigned neatly to one discipline. The Academy's structure, with specialised institutes under a common umbrella, gives it a distinctive ability to organise such cooperation. However, this ability must be actively maintained. Interdisciplinarity does not happen automatically because institutes are listed in the same organisation. It requires incentives, shared language, project structures, leadership, and time for researchers to understand one another's assumptions.

Internationalisation strengthened the computational turn. AI, machine learning, numerical mathematics, image processing, and data science are global fields with fast-changing standards. Czech Academy researchers must participate in international conferences, European projects, software communities, and collaborative networks. At the same time, they bring to these networks a specific institutional heritage: Czech traditions in mathematics, cybernetics, control, numerical analysis, and information theory. This combination of global participation and local continuity is important. It prevents the Academy from becoming merely a consumer of imported computational tools and allows it to contribute methods, theory, and applications from its own research culture.

The public visibility of computation is greater today than at any earlier point in the Academy's history. Artificial intelligence, automated decision-making, digital misinformation, cyber-physical systems, and data privacy are topics of public debate, not only academic research. Institutes such as UTIA and the Institute of Computer Science increasingly participate in outreach, media discussion, and public explanation of AI and related technologies (*Institute of Information Theory and Automation, n.d.*). This communicative role matters because society often encounters computational methods through exaggerated hopes or fears. A public academy can provide more sober interpretation, explaining both the power and the limits of algorithms. This is part of its democratic responsibility in a data-driven age.

The growth of computational and interdisciplinary methods therefore marks a major stage in the Academy's modernisation. It connects older mathematical traditions with new scientific practices; it makes institutes interact across disciplinary boundaries; it gives research new instruments of prediction and interpretation; and it creates public responsibilities around data, AI, and modelling. Yet this growth does not mean that computation replaces scientific judgement. The deepest lesson of the Academy's experience is the opposite. Computation is powerful only when joined to theory, experiment, institutional memory, and domain knowledge. Interdisciplinarity is productive only when participants retain enough disciplinary seriousness to contribute something real.

Thus, the expansion of computational and interdisciplinary methods within the Czech Academy of Sciences shows how the institution adapted to one of the defining transformations of contemporary knowledge. Through the Institute of Mathematics, the Institute of Computer Science, the Institute of Information Theory and Automation, and their cooperation with physical, chemical, biological, environmental, technical, social, and humanities institutes, the Academy created a methodological network capable of modelling complex systems, analysing data, developing artificial intelligence, processing images and signals, and supporting research across disciplinary borders. This development did not erase the Academy's older traditions; it reactivated them in new contexts. Czech traditions of analysis, numerical mathematics, cybernetics, information theory, automation, and computer science became the foundations of a modern interdisciplinary research culture. In this sense, computation became not merely a technical tool of the Academy, but one of the main forms through which its scientific autonomy, public relevance, and international integration are now expressed.

Earth, Space, and Environmental Sciences

1. Geology, Geophysics, Atmospheric Research, and Climate

The Earth, space, and environmental sciences within the Czech Academy of Sciences occupy a position that is both ancient and modern. They deal with the oldest temporal horizons accessible to scientific reconstruction, from the formation of rocks and basins to the evolution of landscapes, climates, organisms, and planetary environments. At the same time, they are among the most urgent sciences of the contemporary world because they address climate change, environmental risk, seismic activity, atmospheric processes, natural hazards, land-use transformation, and the human alteration of the Earth system. This double temporality gives them a special place in the Academy's history. They are sciences of deep time and sciences of immediate public responsibility. Their institutional development shows how the Academy moved from descriptive and regional traditions of geology and geophysics towards integrated Earth-system research, atmospheric modelling, climate-impact studies, and space-related observation. In this respect, they connect the older natural history of the Czech lands with the global environmental agenda of the 21st century (*Akademie věd České republiky, n.d.*; *Global Change Research Institute, n.d.*).

The Czech Academy's own description of earth-science research emphasises two major scales: global-continental and local-regional. Global-continental research concerns the composition, structure, and evolution of the Earth as a planetary body, including its envelopes, while local-regional research focuses on the internal structure of the territory of the Czech Republic, which is described as a geological formation unique in Europe (*Akademie věd České republiky, n.d.*). This formulation is historically important because it captures the tension that has shaped Czech earth sciences for generations. On the one hand, Czech researchers study universal geological and geophysical processes: plate movement, lithospheric structure, palaeoclimate, geodynamics, atmospheric circulation, and global change. On the other hand, their expertise is deeply rooted in the specific geological, geomorphological, and

environmental conditions of Bohemia, Moravia, and Silesia. The Academy's earth sciences therefore developed as a bridge between national territory and planetary science.

Geology was one of the disciplines through which the Czech lands were first scientifically read as a historical landscape. The study of rocks, sediments, fossils, tectonic structures, mineral resources, karst systems, and Quaternary deposits connected natural science with the cultural and economic history of the region. Long before the modern Czech Academy, geological research had been linked to mining, mapping, industrial development, agriculture, water management, and national scholarly culture. The Academy inherited this older tradition and placed it within a research-institute framework. The Institute of Geology of the Czech Academy of Sciences became a central institution for the interpretation and integration of knowledge about the Earth system and its geological and biological past (*Institute of Geology, n.d.*). Its mission is especially revealing because it does not treat geology as a narrow study of rocks alone. It connects endogenous and exogenous geological processes, the development of biota, and anthropogenic effects within a single Earth-system perspective.

This Earth-system perspective represents a major conceptual shift. Classical geology often proceeded by describing strata, structures, fossils, and regional formations. Modern geology still depends on those foundations, but it increasingly interprets them within wider systems of climate, life, erosion, sedimentation, tectonics, environmental change, and human activity. The geological past becomes relevant not only because it explains how the present landscape came into being, but because it gives context for contemporary environmental processes. Sedimentary records may preserve evidence of earlier climates; fossil assemblages may illuminate biological responses to environmental shifts; geomorphological structures may reveal hazard-prone landscapes; and mineralogical or geochemical studies may help interpret pollution, weathering, and material cycles. The Academy's geological research therefore participates in a broader transformation of geology from a primarily historical discipline into an integrative science of the Earth system.

The Czech geological context is particularly rich because the territory of the Czech Republic contains the meeting points and remnants of several major European geological histories. The Bohemian Massif, the Western Carpathians, volcanic regions, sedimentary basins, karst areas, coal-bearing formations, and Quaternary landscapes provide a dense natural archive. For the Academy, this archive is not merely local material for national study. It is also a laboratory for European and global questions. Research on palaeoenvironments, tectonic evolution, sedimentary processes, palaeontology, geochemistry, and geomorphology can use Czech evidence to address wider problems in Earth history. The "local" thus becomes scientifically universal when interpreted through rigorous methods and international comparison. This is one of the recurrent patterns of Czech Academy science: national territory provides empirical specificity, while scientific interpretation links it to global knowledge.

The Institute of Geology's research profile reflects this combination of local depth and conceptual breadth. Its work includes studies of the Earth system and its geological and biological past, with attention to the interaction of internal and external geological processes, biotic development, and anthropogenic effects (*Institute of Geology, n.d.*). Such research is important for understanding the present environment because geological history determines soil formation, water circulation, slope stability, mineral composition, landscape evolution, and ecological potential. It also helps society understand that environmental problems do not occur on an empty surface. They occur in landscapes shaped by millions of years of geological

processes and by centuries of human transformation. Geology therefore gives environmental policy a memory deeper than ordinary political or economic time.

The Institute of Rock Structure and Mechanics adds another crucial dimension to this geological landscape. It focuses on the structure and properties of rocks and rock environments, and also studies glasses, technical ceramics, composites, biomaterials, and issues of inorganic and organic waste processing (*Institute of Rock Structure and Mechanics, n.d.*). This institute sits at the boundary between geology, geomechanics, materials science, engineering, and environmental technology. Its work shows that rocks are not only historical records but also mechanical bodies affected by stress, deformation, fracture, weathering, water, temperature, and human intervention. In a country with mining legacies, underground structures, landslide hazards, industrial waste, and infrastructure needs, such research has clear public relevance. Yet its scientific basis remains fundamental: understanding how rock environments behave requires theory, experiment, monitoring, and modelling.

Rock mechanics and engineering geology also connect the Academy's earth sciences with risk. Landslides, subsidence, rockfalls, underground deformation, seismicity induced by human activity, and instability of slopes or cavities are not purely academic topics. They affect settlements, transport, energy infrastructure, mining areas, and cultural landscapes. The Academy's capacity to study such phenomena gives it a role in national expertise that differs from ordinary project consultancy. It can investigate underlying mechanisms, long-term behaviour, and methodological principles. This is important because risk cannot be understood only at the moment of disaster. It must be read through the slow accumulation of geological, mechanical, climatic, and anthropogenic factors. Earth science here becomes a form of public foresight.

Geophysics extends the study of the Earth into processes that are often invisible at the surface. The Institute of Geophysics of the Czech Academy of Sciences defines its mission as fundamental and applied research in the Earth sciences, the maintenance of Earth-observation facilities, and public engagement on issues of high societal importance (*Institute of Geophysics, n.d.*). Its work belongs to a tradition that reaches back to the early Czechoslovak Republic, when geophysical observation, seismology, geomagnetism, and geodetic measurement were linked to the scientific understanding of the national territory. In the Academy, geophysics developed into a field that combines observation, theory, instrumentation, and modelling. It studies the structure, dynamics, and physical fields of the Earth, including seismic, geomagnetic, geodynamic, and geothermal phenomena.

Seismology is among the most publicly recognisable branches of this work. Although the Czech Republic is not among the world's most seismically active countries, seismic monitoring remains essential. The region contains natural seismicity, earthquake swarms, tectonic structures, and possible induced seismic effects connected with human activities. The Academy's geophysical networks allow researchers to detect, locate, interpret, and compare seismic events. They also connect Czech observations with international data exchange. This matters because even moderate seismicity can reveal important information about crustal structure, fluid movement, fault systems, and geodynamic processes. Seismology in the Academy is therefore both a national monitoring responsibility and a contribution to the global science of the Earth's interior.

The maintenance of observational networks gives geophysics a distinctive institutional character. Unlike some laboratory sciences, geophysics depends heavily on continuous

records: seismic stations, geomagnetic observatories, geodynamic measurements, geothermal observations, and other monitoring systems. A gap in observation may mean the loss of information that cannot be recreated later. The Academy's role is therefore not only to interpret data but to preserve continuity of measurement. This gives geophysical research a temporal discipline comparable to climatology and astronomy. Long records are scientific assets. They allow researchers to distinguish anomalies from trends, events from background behaviour, and local signals from broader geophysical processes.

Geophysics also connects the Academy to international services and data centres. Earth's physical fields do not stop at national borders, and neither can their scientific interpretation. Seismic waves travel across continents; geomagnetic disturbances are linked to solar and magnetospheric activity; geodynamic processes form part of regional and global tectonic systems. Czech geophysical observations therefore become valuable when integrated into wider networks. The Academy's national service role is inseparable from international cooperation. This is a recurring feature of modern Earth science: a national institute may be responsible for local observation, but the meaning of its data often emerges only through global comparison.

Atmospheric research forms another major pillar of this section. The Institute of Atmospheric Physics of the Czech Academy of Sciences studies processes in the Earth's atmosphere and near space (*Institute of Atmospheric Physics, n.d.*). This formulation is important because it places atmospheric science between terrestrial environmental research and space physics. The atmosphere is not merely the air above the landscape. It is a dynamic, stratified, chemically active, electrically complex, and solar-influenced system connecting Earth to near-Earth space. Research at the Institute includes meteorology, climatology, boundary-layer processes, cloud and precipitation physics, atmospheric dynamics, ionosphere and aeronomy, and the interaction of the atmosphere with solar and magnetospheric phenomena. The Academy's atmospheric research thus spans the surface, the troposphere, the upper atmosphere, and near space.

The Milešovka observatory symbolises the importance of long-term atmospheric observation. As the oldest mountain meteorological observatory in the Czech Republic, with measurements beginning in 1905, it represents a historical continuity that predates the modern Academy but became part of the country's scientific infrastructure (*Institute of Atmospheric Physics, n.d.*). Such observatories are irreplaceable because climate and atmospheric variability can be understood only through long, carefully maintained records. The value of an observatory increases with time, provided that measurements remain reliable and comparable. In the Academy's history, Milešovka is therefore more than a station. It is a witness to the transformation of meteorology from descriptive observation into climate science, boundary-layer research, and environmental expertise.

Atmospheric physics also links the Academy to space science. The Institute of Atmospheric Physics has a tradition connected with ionospheric and magnetospheric research, including the MAGION satellites and participation in missions such as Solar Orbiter, where high-frequency electromagnetic waves in the solar wind and interplanetary dust particles are studied (*Institute of Atmospheric Physics, n.d.*). This connection shows that Earth science and space science cannot be sharply separated. Solar wind, geomagnetic storms, ionospheric disturbances, and upper-atmospheric processes affect radio communication, satellite operation, navigation systems, and the physical environment of near-Earth space. Czech

atmospheric research therefore belongs not only to meteorology and climate studies, but also to the wider field of space weather and planetary environments.

The Astronomical Institute of the Czech Academy of Sciences adds a further space-related dimension to this picture. It is a modern public research organisation for astronomy and astrophysics and carries out a major part of Czech research in those fields, with research extending from the immediate environs of the Earth to distant galaxies and black holes (*Astronomical Institute, n.d.*). Although astronomy is treated more directly in the broader space-science context, its connection with atmospheric and Earth sciences is real. Meteor observations, interplanetary matter, solar physics, solar activity, and near-Earth objects all connect the Earth to the wider Solar System. The Academy's research on meteors and minor bodies, for example, links planetary history, impact risk, atmospheric entry, and the material history of the Solar System. Space is therefore not an abstract distance from Earth; it is part of the environment in which Earth exists.

Climate research represents the most contemporary and politically charged development in this whole domain. The climate system is not merely a meteorological average; it is an interacting system of atmosphere, oceans, land, cryosphere, biosphere, and human activity. The IPCC's 7th Assessment Report synthesised the state of global climate knowledge and confirmed the central role of human influence in observed climate change (*IPCC, 2021*; *IPCC, 2023*). For the Czech Academy, climate research has a specific institutional expression in the Global Change Research Institute, known as CzechGlobe. CzechGlobe investigates current and future manifestations of global change in the atmosphere, ecosystems, and human society, using methods ranging from molecular-level analysis to satellite imagery (*Global Change Research Institute, n.d.*). This range shows that climate science in the Academy is not confined to atmospheric physics alone. It is a multidisciplinary field connecting biogeochemistry, ecology, remote sensing, socio-economic impacts, climate services, and environmental risk.

CzechGlobe's focus on energy and substance fluxes, especially greenhouse gases, places it at the centre of Earth-system research (*Global Change Research Institute, n.d.*). Greenhouse-gas fluxes are not abstract quantities. They are produced and absorbed by forests, soils, wetlands, agricultural systems, cities, industrial activity, and atmospheric transport. Measuring and modelling them requires field stations, eddy-covariance towers, atmospheric monitoring, remote sensing, ecological experiments, laboratory analyses, and statistical modelling. The Academy's climate-related research therefore depends on a combination of observation and interpretation. It must measure what is happening in real landscapes while also modelling how those processes may develop under future climate scenarios. This gives climate science a public importance that few other fields possess.

The rise of CzechGlobe also shows how environmental science moved beyond the older division between natural and social sciences. Global change includes climate, land productivity, atmospheric chemistry, ecosystems, and the socio-economic systems that both drive and suffer from environmental transformation (*Global Change Research Institute, n.d.*). In this sense, the Academy's climate science cannot be understood as physical science alone. It also requires knowledge of agriculture, forestry, water management, urban environments, health risks, economics, adaptation policy, and social resilience. This is one of the reasons why climate research is institutionally challenging. It requires a scientific culture capable of

crossing boundaries while maintaining methodological seriousness in each field. The Academy's multi-institute structure gives it a strong basis for such work.

The connection between atmospheric research and climate science is especially important. Weather and climate are distinct, but they are physically connected through atmospheric circulation, radiation, moisture, clouds, aerosols, land-surface interactions, and oceanic influences. The Institute of Atmospheric Physics contributes to understanding atmospheric processes, while CzechGlobe focuses on global change, greenhouse gases, ecosystems, and impacts. Together, these institutions show how the Academy covers both the physics of atmospheric behaviour and the broader consequences of climate transformation. This division of labour is productive because it allows atmospheric mechanisms and environmental impacts to be studied in relation to one another. Climate change is not only a trend in temperature. It is a change in the behaviour of systems that affect drought, floods, heatwaves, ecosystems, agriculture, forests, and human settlements.

The Czech regional context gives climate research a particular urgency. Central Europe is sensitive to drought, heat extremes, forest stress, soil-water changes, urban heat islands, and changes in agricultural productivity. These issues cannot be solved by global climate models alone. They require regional observation, downscaling, impact modelling, and knowledge of local landscapes. CzechGlobe's climate and climate-risk portals, including work on climatic conditions, meteorological extremes, and their impacts on agriculture, forestry, water regime, and landscape, demonstrate this applied dimension of Academy research (*Global Change Research Institute, n.d.*). Yet this applied orientation rests on fundamental scientific capacities. Reliable climate services require good data, strong models, ecological understanding, and long-term monitoring.

The Academy's earth and climate sciences therefore operate at multiple time-scales. Geology studies processes unfolding across millions of years. Geophysics records events that may occur in seconds but arise from deep tectonic histories. Atmospheric science observes minutes, days, seasons, and long-term climatic series. Climate research examines decades, centuries, and future scenarios. Environmental science connects these natural time-scales with human decision-making, which often operates under political and economic pressure. The Academy's value lies partly in its ability to hold these time-scales together. It reminds society that present choices occur within histories much longer than ordinary public debate recognises.

Methodologically, these sciences also connect fieldwork, observation, laboratory analysis, modelling, remote sensing, and computation. Geological mapping and palaeontological interpretation require direct engagement with landscapes and specimens. Geophysics depends on instruments and continuous signals. Atmospheric research uses observatories, radars, satellites, models, and theoretical physics. Climate science integrates field measurements, ecosystem experiments, greenhouse-gas monitoring, satellite imagery, socio-economic analysis, and scenario modelling. The Academy's institutes therefore represent different modes of knowing the Earth: collecting, measuring, drilling, mapping, modelling, comparing, and forecasting. This methodological plurality is one of the strengths of the field. It prevents environmental knowledge from becoming either purely abstract or merely descriptive.

The post-socialist transformation affected these fields in distinctive ways. Geology and geophysics inherited strong Czechoslovak traditions, including mapping, seismology, mineral

research, palaeontology, geodynamics, and engineering geology. Atmospheric research inherited long observational records and expertise in meteorology, ionosphere, and near-space studies. After 1989, these traditions had to be reconnected with European frameworks, international publication standards, research infrastructures, competitive grants, and global environmental agendas. Climate science, in particular, gained new importance as environmental questions moved from the margins of policy to the centre of international debate. The Academy's earth sciences thus shifted from national description and sectoral expertise towards global environmental participation.

This transformation also changed the relationship between the Academy and the state. Earth, atmospheric, and climate sciences are not politically neutral in their consequences, even when their methods are rigorously scientific. They provide evidence relevant to land-use planning, hazard management, climate adaptation, energy policy, water resources, agriculture, forestry, infrastructure, and environmental protection. The Academy's public research status gives it a special responsibility to provide expertise that is independent, long-term, and methodologically credible. In these fields, scientific autonomy is not a withdrawal from public life. It is the condition under which public advice can be trusted.

At the same time, these sciences must communicate uncertainty. Geological hazards, seismic risk, climate projections, weather extremes, ecosystem responses, and environmental impacts all involve uncertainty. Public discussion often demands simple answers, but responsible science must distinguish between what is known, what is probable, what is model-dependent, and what remains uncertain. The Academy's role is not to eliminate uncertainty by rhetorical force, but to make it scientifically intelligible. This is especially important in climate science, where uncertainty can be misused either to exaggerate confidence or to deny robust conclusions. A public academy must maintain a language of evidence, confidence, probability, and limitation.

The Earth, space, and environmental sciences also deepen the Academy's international role. Geological correlations, seismic networks, atmospheric observations, space missions, greenhouse-gas monitoring, and climate-impact studies all require cross-border cooperation. Czech institutes contribute data, methods, expertise, and regional knowledge to European and global systems. At the same time, they receive models, satellite products, international standards, and comparative frameworks from abroad. This reciprocal relation is one of the defining features of modern Earth science. No country studies the Earth alone. Yet each country's observations matter, because global knowledge depends on distributed local competence.

The cultural meaning of these sciences is also significant. They place the Czech lands within deep natural history and within planetary processes. Geology tells society that its landscapes are historical formations, not merely economic spaces. Geophysics reveals that the apparent stability of the ground rests on dynamic processes. Atmospheric science shows that the air above the country is part of a layered and global system. Space research situates Earth within solar and cosmic environments. Climate science demonstrates that human society is now a geological and atmospheric force. The Academy's work in these fields therefore contributes not only to policy and technology but to a changed understanding of humanity's place in nature.

Thus, geology, geophysics, atmospheric research, and climate science within the Czech Academy of Sciences form an integrated domain of knowledge in which deep time, national

territory, planetary processes, and contemporary public responsibility meet. The Institute of Geology, the Institute of Rock Structure and Mechanics, the Institute of Geophysics, the Institute of Atmospheric Physics, the Astronomical Institute, and CzechGlobe together show how the Academy studies the Earth from its rocks and crust to its atmosphere, near-space environment, ecosystems, and climate future. These fields preserve older Czechoslovak traditions of observation, mapping, seismology, meteorology, and natural history, but they also transform them through modelling, remote sensing, global-change research, international networks, and public expertise. In this sense, the Academy's earth and environmental sciences are not a peripheral extension of natural science. They are one of the central arenas in which the Academy defines its responsibility to the Czech lands, to Europe, and to the planetary conditions of human life.

2. Environmental Monitoring and Long-Term Scientific Expertise

Environmental monitoring is one of the least spectacular but most decisive functions of the Czech Academy of Sciences. It rarely produces a single dramatic discovery that can be narrated as a breakthrough, yet it creates the evidential foundations without which environmental science, public policy, risk assessment, and climate adaptation would remain fragile. Monitoring means returning to the same places, measuring comparable variables, maintaining instruments, preserving data, interpreting trends, and distinguishing short-term fluctuation from long-term change. It is therefore a form of scientific patience. In the Academy, environmental monitoring connects geology, geophysics, atmospheric physics, hydrology, ecology, botany, hydrobiology, climate research, and data science. Its institutional value lies in the fact that many environmental processes become visible only when knowledge is accumulated across years, decades, and sometimes generations (*Akademie věd České republiky, n.d.*; *Global Change Research Institute, n.d.*).

The Academy's role in monitoring differs from the role of administrative agencies or emergency services. State agencies often operate official monitoring systems required for regulation, public warnings, water management, meteorology, or environmental compliance. The Academy does not replace these functions. Its distinctive contribution is to produce research-grade monitoring, to develop methods, to interpret complex processes, and to preserve long-term expertise that can support both national and international knowledge systems. Academy monitoring is therefore not merely data collection. It is the creation of scientific continuity. It gives society the ability to ask how landscapes, ecosystems, waters, atmosphere, soils, seismic zones, and climate risks are changing, and why those changes matter.

This long-term function is especially important in environmental science because the environment is never static. Rivers respond to rainfall, drought, land use, pollution, and regulation. Forests respond to temperature, pests, soil chemistry, management, and atmospheric deposition. Lakes respond to nutrient loads, climate, fish communities, and internal biogeochemical cycles. The atmosphere responds to circulation, aerosols, greenhouse gases, radiation, and local land-surface processes. Seismic networks record sudden events, but their interpretation depends on background knowledge accumulated over time. Environmental monitoring therefore requires both temporal depth and disciplinary breadth. The Academy's multi-institute structure gives it the capacity to sustain this breadth without reducing complex environmental systems to one administrative category.

The Institute of Geophysics provides one of the clearest examples of monitoring as public scientific expertise. Its mission includes fundamental and applied research in the Earth sciences, maintenance of a network of Earth-observation facilities, dissemination of scientific outcomes, and public engagement on issues of high societal importance (*Institute of Geophysics, n.d.*). This mission expresses the double role of geophysical observation. On the one hand, seismic, geomagnetic, geodynamic, and related data are research materials for understanding the Earth's crust, lithosphere, geodynamics, magnetism, volcanism, tectonics, and surface processes. On the other hand, they are part of the knowledge infrastructure through which society can recognise and interpret natural hazards. The Academy's geophysical monitoring therefore connects pure research with civic responsibility.

Seismology illustrates this connection particularly well. The Department of Seismology of the Institute of Geophysics operates the Czech Regional Seismological Network, the local seismic network WEBNET in West Bohemia and Vogtland, and other regional and international networks. The Czech Regional Seismological Network monitors earthquakes in West Bohemia, near Hronov, and in northern Moravia and Silesia, as well as other seismic events such as rockbursts and mine explosions; it consists of more than 20 permanent broadband stations located in the Czech Republic (*Institute of Geophysics, n.d.*). WEBNET, operated by the Institute of Geophysics and the Institute of Rock Structure and Mechanics, consists of 23 stations, most of them streaming data in real time (*Institute of Geophysics, n.d.*). These systems show how a research institute becomes a national custodian of signals that might otherwise remain invisible until they become crises.

The significance of such seismic monitoring lies not only in detecting earthquakes. It also enables the study of earthquake generation, wave propagation, crustal and upper-mantle structure, natural and induced seismicity, and macroseismic effects felt by citizens. The seismic service localises regional and global earthquakes, analyses seismograms, ensures international data exchange and archiving, and collects macroseismic data from events felt in Czechia (*Institute of Geophysics, n.d.*). This is a form of long-term scientific memory. A single earthquake may attract public attention, but its scientific meaning depends on comparison with earlier events, station histories, geological context, and models of the subsurface. The Academy's expertise turns individual events into knowledge about processes.

Geophysical monitoring also demonstrates why environmental expertise cannot be organised only around visible ecological change. The environment includes hidden structures and forces: stresses in rocks, fluid movements in the crust, geomagnetic variations, induced seismic effects, and the interaction between natural systems and human activities such as mining, drilling, geothermal exploration, and underground storage. The Academy's geophysical networks make these hidden dynamics observable. This matters for public safety, infrastructure planning, and scientific understanding. It also shows that environmental science is not only about landscapes and ecosystems, but about the physical stability and dynamics of the territory itself.

Atmospheric observation represents another major form of long-term expertise. The Institute of Atmospheric Physics maintains and develops research in meteorology, atmospheric dynamics, boundary-layer processes, cloud and precipitation physics, ionosphere and aeronomy, and near-space processes (*Institute of Atmospheric Physics, n.d.*). Its Milešovka observatory is especially significant because it is the oldest mountain meteorological observatory in the Czech Republic, with measurements beginning in 1905 (*Institute of*

Atmospheric Physics, n.d.). Such long observational series are scientific treasures. They provide continuity across political regimes, institutional reforms, changes in technology, and changes in scientific language. The atmosphere has been measured there through the late Habsburg period, the First Czechoslovak Republic, occupation, state socialism, the Velvet Revolution, and the modern Czech Republic.

The long-term importance of Milešovka lies in the possibility of comparing present atmospheric conditions with more than a century of observations. Climate change cannot be understood from a few hot summers or isolated extreme events. It requires long records that allow scientists to place anomalies within historical distributions. Mountain observatories are especially valuable because they record conditions less directly shaped by local urban environments than many lowland stations. They help researchers study cloudiness, precipitation, wind, temperature, visibility, and boundary-layer processes in a setting sensitive to regional atmospheric circulation. The Academy's maintenance of such observatories is therefore not a conservative attachment to old instruments, but an active contribution to climate and atmospheric science.

The connection between Milešovka and ACTRIS-CZ shows how older observational traditions are being integrated into modern European research infrastructures. The Institute of Atmospheric Physics describes the aim of its participation in ACTRIS-CZ as the establishment and long-term operation of an observational platform at Milešovka capable of meeting ACTRIS standards (*Institute of Atmospheric Physics, n.d.*). This is institutionally significant because it transforms a national long-term station into part of a European infrastructure for atmospheric composition, aerosols, clouds, and trace gases. The value of a historical observatory increases when its data can be standardised, compared, and integrated with international networks. In this way, the Academy links local continuity to European atmospheric science.

Climate and global-change monitoring have become one of the strongest contemporary expressions of the Academy's environmental expertise. The Global Change Research Institute, CzechGlobe, focuses on the manifestations and impacts of global change in the atmosphere, ecosystems, and human society, using methods that range from molecular-level analysis to satellite imagery (*Global Change Research Institute, n.d.*). Its monitoring activities include greenhouse gases and pollutants, ecosystem carbon fluxes, drought, vegetation condition, yield forecasts, fire risk, climate extremes, and adaptation-support tools. This breadth is important because global change is not one variable. It is a system of interacting atmospheric, ecological, hydrological, agricultural, and socio-economic processes. Monitoring it requires a distributed scientific architecture.

CzechGlobe's public portals are especially important for translating long-term expertise into usable knowledge. InterSucho combines ground-based measurements, a dynamic water-balance model, remote sensing methods, and observations from a wide network of reporters to monitor and forecast soil drought (*Global Change Research Institute, n.d.*). The ClimRisk and Climate Change portals provide information about the long-term development of climatic conditions, meteorological extremes, and impacts on agriculture, forestry, the water regime, and landscape (*Global Change Research Institute, n.d.*). Early-warning systems monitor vegetation, yields, abiotic and biotic crop risks, and fire risk. These systems show that environmental monitoring is not only retrospective. It is also anticipatory. It helps farmers, foresters, municipalities, planners, and public authorities prepare for risks before they become irreversible damage.

Drought monitoring is particularly important in Central Europe. Drought is not a single event but a sequence of deficits in precipitation, soil moisture, streamflow, groundwater, vegetation condition, crop productivity, and ecosystem resilience. A dry year may be damaging, but repeated droughts can restructure forests, agriculture, water management, and rural economies. The Academy's drought-monitoring systems help distinguish meteorological drought from agricultural and ecological consequences. They integrate measurement, modelling, remote sensing, and field observations. This integration is vital because drought is experienced locally but driven by regional atmospheric and hydrological processes. The Academy's expertise gives Czech society a more precise language for a risk that is likely to remain central under climate change.

Greenhouse-gas monitoring forms another crucial dimension. CzechGlobe's Domain of Ecosystem Analyses focuses on monitoring greenhouse gases and air pollutants in the atmosphere and their long-range transport; it also gathers and analyses information on carbon fluxes, sequestration, and storage at ecosystem and landscape scales and contributes to major global databases (*Global Change Research Institute, n.d.*). The large research infrastructure CzeCOS provides a platform for international interdisciplinary research on global change and its impacts on ecosystems, contributing to Czech obligations in research, adaptation, and mitigation (*CzeCOS, n.d.*). Its ecosystem stations are equipped according to ICOS protocol for measuring fluxes of carbon dioxide, nitrous oxide, methane, water, and energy between terrestrial ecosystems and the atmosphere, along with climatic characteristics and related variables (*Global Change Research Institute, n.d.*). This kind of monitoring connects Czech landscapes to the global carbon cycle.

Participation in ICOS gives this work a European and international framework. The ICOS Czech Republic network comprises one Atmosphere station and three Ecosystem stations, conducting long-term research on greenhouse gases and carbon cycles in the atmosphere and in Czech ecosystem types such as floodplain forest, evergreen needle-leaf forest, and wetland (*ICOS, n.d.*). The broader ICOS infrastructure offers open access to high-quality, standardised greenhouse-gas data and scientific products (*ICOS, n.d.*). This matters because carbon-cycle knowledge depends on comparability. A flux measurement in a Czech forest gains global meaning only when it can be interpreted alongside measurements in other European ecosystems and atmospheric stations. The Academy's contribution is therefore both national and planetary.

Hydrological monitoring is another area where long-term expertise is indispensable. The Institute of Hydrology of the Czech Academy of Sciences, formerly known in English as the Institute of Hydrodynamics, presents its scientific activities as fully oriented towards water issues, including water balance, rainfall–runoff processes in basins, hydrological monitoring, water in soil, wetland hydrology, water treatment, micropollutants, and water-quality problems (*Institute of Hydrology, n.d.*). Its description of hydrological monitoring is especially direct: monitoring is a basic prerequisite for understanding the water cycle in the landscape and for describing and quantifying the processes involved (*Institute of Hydrology, n.d.*). This statement captures the essence of environmental monitoring. Without repeated observation, hydrology becomes speculation about a system that is constantly moving.

Water connects climate, geology, soil, vegetation, settlement, agriculture, industry, and public health. The Academy's hydrological expertise therefore has many layers. It includes rainfall–runoff processes, soil hydrology, wetland water regimes, water retention, flood and drought

behaviour, natural organic matter, micropollutants, microplastics, PFAS, treatment technologies, and water purification. This work is not limited to environmental description. It provides knowledge for water management, drinking-water safety, wastewater treatment, landscape adaptation, and protection of water resources. In a changing climate, water expertise becomes one of the most important forms of public science. The Academy's role is to maintain research depth in a field where political attention often rises only during crises.

The Institute of Hydrology's work on wetland hydrology is a good example of how monitoring can challenge public assumptions. Wetlands are often described simply as natural sponges that retain water, but their actual hydrological behaviour depends on peat structure, soil properties, vegetation, rainfall patterns, slope, catchment context, and seasonal conditions. Studies of peatland and forest-soil hillsides show that different landscape elements may respond very differently to precipitation events and that environmental tracers and hydrological models are needed to understand these differences (*Akademie věd České republiky, 2024*). Such research matters because adaptation policies often rely on simplified ideas about "nature-based solutions". The Academy's expertise helps make those solutions scientifically realistic.

Aquatic ecosystems add another long-term monitoring tradition. The Institute of Hydrobiology at the Biology Centre of the Czech Academy of Sciences has roots in early Czechoslovak Academy hydrobiological research and pursues long-term projects focused on biological processes in reservoirs, including eutrophication, plankton communities, microbial loops, water blooms, phosphorus load, lake turnover, and atmospheric acidification of mountain lakes (*Biology Centre, n.d.*). These topics are crucial because reservoirs and lakes are sensitive indicators of environmental change. They integrate signals from catchments, climate, nutrient inputs, fish communities, sediment processes, and human management. A lake or reservoir is therefore not a static water body but a dynamic ecological archive.

Long-term hydrobiological expertise is especially important for eutrophication. Nutrient enrichment can alter plankton composition, trigger algal blooms, reduce water quality, affect oxygen conditions, and change food webs. Its effects may persist even after external nutrient inputs are reduced, because internal loading from sediments and biological feedbacks can maintain degraded states. Monitoring allows researchers to understand these delayed and interacting processes. It also provides public authorities with knowledge needed for water protection, fisheries management, reservoir operation, and biodiversity conservation. The Academy's hydrobiological work thus links fundamental ecology with very practical questions of water quality and ecosystem management.

Modern hydrobiology has also become a data-rich field. Fish telemetry, hydroacoustics, stable isotopes, plankton monitoring, microbial analysis, and long-term reservoir datasets allow researchers to study aquatic ecosystems with increasing precision. The Biology Centre's work on lake fish telemetry and large datasets of tracked fish positions shows how environmental monitoring now intersects with big data and behavioural ecology (*Biology Centre, 2022*). This is a major methodological change. Monitoring is no longer only the periodic sampling of water or organisms; it can involve continuous or high-resolution observation of movement, behaviour, trophic interactions, and ecosystem dynamics. The Academy's hydrobiological expertise therefore belongs to the same computational turn described in the mathematical and data-science section of this chapter.

Botanical and biodiversity monitoring represent another major area of long-term expertise. The Institute of Botany of the Czech Academy of Sciences is the largest botanical research centre in the Czech Republic and contributes to research and nature conservation in the Czech Republic and abroad (*Institute of Botany, 2022*). Botanical expertise depends on continuity because plant distributions, vegetation types, invasive species, forest dynamics, and local biodiversity patterns change slowly, unevenly, and often in response to multiple drivers. Field records, herbarium knowledge, vegetation plots, species traits, historical literature, and digital databases all become part of the monitoring apparatus. In this domain, long-term expertise includes not only instruments but also taxonomic judgement and memory of landscapes.

The PLADIAS database is one of the most important examples of this modernised botanical expertise. It was developed to create an integrated database and online information system on plant diversity in the Czech Republic, linked to international databases and used to test hypotheses about the evolution and maintenance of temperate plant diversity across scales (*Institute of Botany, n.d.*). The database focuses on native and naturalised flora of the Czech Republic and provides information on distribution maps, plant traits, vegetation types, descriptions, maps, and species composition (*PLADIAS, n.d.*). Its aim is to support scientific research, education, nature conservation, and environmental assessment (*PLADIAS, n.d.*). This is environmental monitoring in a digital form: not a single station or instrument, but a curated knowledge system.

PLADIAS also shows how historical and contemporary data can be integrated. Plant distribution records, traits, vegetation classification, taxonomic concepts, bibliographies, and digital maps allow researchers and conservationists to ask questions about biodiversity change, species invasions, habitat loss, climate responses, and landscape history. Such databases transform scattered observations into usable scientific infrastructure. They also demonstrate that long-term expertise is not only about measuring the same variable repeatedly. It may also involve maintaining taxonomic standards, verifying records, linking old literature to new data, and making information accessible for conservation and policy. The Academy's botanical expertise therefore preserves a national biodiversity memory while opening it to modern analysis.

Environmental monitoring also reaches beyond the borders of the Czech Republic. CzechGlobe's ecosystem stations and collaborations in Ghana and Vietnam, the Institute of Botany's long-term tropical monitoring, and the Biology Centre's international biodiversity and aquatic collaborations show that Academy expertise is not confined to national territory (*Global Change Research Institute, 2023*; *Institute of Botany, n.d.*; *Biology Centre, 2022*). This international dimension is important because global change is not a set of isolated national problems. Tropical forests, wetlands, Central European droughts, lake ecosystems, greenhouse-gas fluxes, and invasive species all belong to interconnected environmental processes. The Academy's long-term expertise becomes more valuable when it is able to compare Czech patterns with global ones.

At the same time, national environmental expertise remains essential. The Czech Republic's landscapes have specific histories: mining, agriculture, forestry, river regulation, industrial pollution, urbanisation, protected areas, reservoirs, and post-socialist land-use changes. Monitoring must therefore be sensitive to local and regional contexts. Imported models are not enough. The Academy's institutes contribute by generating local data, interpreting them through international science, and returning knowledge to Czech society. This is one of the

defining features of a national academy in an interconnected world. It must be able to think globally without abandoning the responsibility to know its own territory.

The environmental expertise of the Academy also has a strong advisory and public-communication dimension. Seismic events felt by citizens, drought warnings, water-quality problems, biodiversity decline, climate risks, invasive species, pollutant monitoring, and landscape adaptation all require communication beyond academic journals. The Academy must explain uncertainty, probability, thresholds, and risk without either minimising or sensationalising environmental problems. This is difficult because environmental questions are often politically charged. Drought affects agriculture; water pollution affects municipalities and industry; biodiversity loss affects land-use policy; climate adaptation affects investment and planning. The Academy's credibility depends on maintaining methodological seriousness and independence in such contexts.

Long-term expertise is also vulnerable. Monitoring networks require stable funding, trained personnel, technical maintenance, data storage, and institutional commitment. A station can be closed quickly, but the loss of its long-term series cannot be repaired. A database can become obsolete if curation stops. Taxonomic expertise can disappear if no new generation is trained. Environmental monitoring therefore depends on institutional memory and strategic protection. The Academy's public research status makes it one of the few institutions capable of sustaining such capacities when immediate political attention shifts elsewhere. This role is especially important in periods when short-term project funding dominates research life.

The post-socialist transformation changed the conditions of monitoring in several ways. It opened Czech environmental science to European infrastructures, international data standards, competitive projects, and cross-border collaboration. It also increased the demand for publicly accountable expertise in areas such as climate change, water management, environmental health, and biodiversity conservation. At the same time, it exposed long-term monitoring to new financial pressures. The Academy had to defend monitoring not merely as routine observation but as the basis of research excellence and public responsibility. In this sense, environmental monitoring became part of the broader struggle to define the modern Academy's mission after 1989.

Environmental monitoring also connects strongly with Strategy AV21. Programmes focused on water, global change, environmental protection, and public-interest research express the Academy's attempt to organise expertise around societal challenges while preserving scientific autonomy (*Strategy AV21, n.d.*). The language of public interest is especially appropriate here. Environmental monitoring is public-interest research in its purest form because its value often becomes obvious only when society faces drought, flood, pollution, seismic events, forest decline, biodiversity loss, or climate extremes. The Academy's task is to produce knowledge before the emergency, not only after it.

The growth of data science further changes the future of monitoring. Remote sensing, automated sensors, telemetry, machine learning, spatial databases, climate portals, and open data systems allow environmental researchers to observe more variables at higher resolution. Yet the basic problem remains interpretative. More data do not automatically produce better understanding. They must be calibrated, validated, compared, archived, and placed within models and field knowledge. The Academy's long-term expertise is therefore more necessary, not less, in the age of data abundance. It provides the judgement needed to turn streams of measurements into evidence.

Thus, environmental monitoring and long-term scientific expertise form one of the central public functions of the Czech Academy of Sciences. Through geophysical networks, mountain meteorological observatories, atmospheric and greenhouse-gas stations, drought and climate-risk portals, hydrological catchments, water-quality laboratories, reservoir studies, botanical databases, biodiversity monitoring, and ecosystem infrastructures, the Academy preserves the temporal continuity of environmental knowledge. This work is less visible than spectacular discoveries, but it is indispensable for understanding change, preparing for risk, and governing the relationship between society and nature. It shows that the Academy's authority rests not only on its ability to produce new theories, but on its capacity to remember, measure, compare, and interpret the changing world over long periods of time.

3. Czech Contributions to Global Environmental Science

Czech contributions to global environmental science emerged from a specific historical position: the Czech Academy of Sciences was never the scientific institution of a great territorial empire or a large global power, but it developed a dense and sophisticated research culture in a country whose landscapes, industrial history, biodiversity, water systems, forests, and climate risks made environmental knowledge unusually concrete. This gave Czech environmental science a particular character. It was strongly rooted in national territory, but it repeatedly turned local observation into knowledge relevant beyond national borders. The Czech lands offered geological complexity, managed forests, agricultural basins, mountain observatories, reservoirs, urban-industrial legacies, polluted and recovered ecosystems, and Central European climate gradients. These conditions became field laboratories for questions that are now global: how ecosystems respond to climate change, how carbon moves between land and atmosphere, how biodiversity is altered by human activity, how water systems react to drought and eutrophication, and how societies can adapt to environmental stress. The Academy's contribution to global environmental science therefore did not lie in abandoning the Czech context, but in making it scientifically comparable, internationally connected, and methodologically useful (*Akademie věd České republiky, n.d.*; *Global Change Research Institute, n.d.*).

This contribution must be understood within the broader transformation of environmental science itself. In the 19th and early 20th centuries, naturalists, botanists, geologists, meteorologists, and hydrologists often studied particular landscapes, species, rocks, rivers, or weather records. By the late 20th century, those older traditions were increasingly reorganised around the concept of global environmental change. Climate change, biodiversity loss, nitrogen deposition, land-use change, invasive species, water scarcity, soil degradation, and atmospheric pollution were no longer treated as separate problems. They became parts of an interconnected Earth system shaped by human activity. The Czech Academy's environmental institutes entered this global scientific culture through long-term monitoring, ecosystem experiments, remote sensing, greenhouse-gas observation, biodiversity databases, climate-risk portals, international collaborations, and contributions to global assessments. Their work shows how a national academy can participate in planetary science by providing high-quality local and regional knowledge within international networks.

The most visible institutional expression of this global orientation is the Global Change Research Institute of the Czech Academy of Sciences, known as CzechGlobe. Its research focuses on the current and future manifestations of global change in the atmosphere,

ecosystems, and human society, using methods ranging from molecular analysis to satellite imagery (*Global Change Research Institute, n.d.*). This range is significant because global change is not a single discipline. It requires atmospheric chemistry, plant physiology, ecosystem ecology, remote sensing, climate modelling, socio-economic analysis, adaptation studies, and policy-relevant communication. CzechGlobe's very institutional form demonstrates that environmental science had moved beyond the older division between natural history, meteorology, forestry, agriculture, and geography. It became a research field in which biophysical and social processes had to be analysed together.

CzechGlobe's work on greenhouse gases and ecosystem carbon fluxes places Czech environmental science inside one of the central problems of global climate science. The exchange of carbon dioxide, methane, water vapour, and energy between ecosystems and the atmosphere is a key part of the global carbon cycle. It cannot be understood only by atmospheric measurement or by satellite observation. It requires field stations, eddy-covariance towers, vegetation measurements, soil analysis, modelling, remote sensing, and long-term data series. Through CzeCOS and ICOS-related activities, Czech researchers contribute observations from forests, wetlands, and other ecosystem types to European and global efforts to quantify carbon and greenhouse-gas dynamics (*CzeCOS, n.d.*; *Integrated Carbon Observation System, n.d.*). This contribution matters because global models depend on distributed measurements. A Czech forest or wetland becomes scientifically global when its fluxes are measured according to international standards and interpreted alongside sites from other regions.

The location of the FLUXNET annual conference in Brno in 2023, organised by CzechGlobe and Mendel University in Brno, symbolised this integration. FLUXNET is a global network of regional networks using eddy-covariance measurements to study carbon, water, and energy exchanges between ecosystems and the atmosphere (*Global Change Research Institute, 2023*; *Integrated Carbon Observation System, 2023*). Hosting such a conference is not merely a matter of prestige. It indicates that Czech environmental science is not peripheral to global ecosystem research. It participates in the methodological debates, data standards, and international communities that shape how the terrestrial biosphere is represented in climate science. The Academy's role here is both empirical and organisational: it supplies observations and helps sustain the scientific networks through which observations become global knowledge.

Remote sensing became another major avenue of Czech contribution. Global environmental science depends increasingly on satellites, airborne platforms, drones, imaging spectroscopy, vegetation indices, land-cover classification, and spatial modelling. CzechGlobe's remote-sensing research connects satellite and airborne data with ecosystem observations, drought assessment, vegetation condition, land-use change, and global-change impacts (*Global Change Research Institute, n.d.*). This is important because remote sensing alone can produce images without interpretation, while field ecology alone can produce detail without sufficient spatial coverage. The Czech contribution lies in linking these scales. By combining field measurements, ecosystem stations, hyperspectral data, and modelling, Czech researchers help translate spatial observation into ecological and climatic evidence.

The SCERIN network and related Earth-system observation activities further illustrate this role. CzechGlobe's hosting of the SCERIN workshop in Brno in 2023 on terrestrial ecosystems, land-cover and land-use change, and driving forces reflected the Academy's participation in international remote-sensing and environmental-observation communities (*Global Change*

Research Institute, 2023). Such meetings are important because global environmental problems require comparable methods across regions. Land-use change in Central Europe, drought effects in agricultural landscapes, forest stress, and urban expansion can be understood more clearly when they are studied with methods that are comparable to those used elsewhere. Czech environmental science thus contributes not only data from Czech territory but also methodological exchange within global Earth-observation science.

Climate-impact and adaptation research is another area in which Czech contributions acquired global relevance. CzechGlobe's work includes climate-risk portals, drought monitoring, yield forecasts, fire-risk monitoring, and assessment of climate impacts on agriculture, forestry, water regimes, and landscapes (*Global Change Research Institute, n.d.*). These tools have direct national value, but their scientific importance reaches further. Central Europe is a region where climate change interacts with intensive agriculture, managed forests, river regulation, urbanisation, and historical land-use change. Studying these interactions helps clarify how temperate societies adapt to heat, drought, forest disturbance, crop stress, and water scarcity. Czech research therefore contributes to the wider European and global question of how middle-latitude regions respond to climate instability.

The participation of CzechGlobe researchers in global assessment bodies deepens this contribution. The Intergovernmental Panel on Climate Change and the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services are not ordinary scientific projects; they are mechanisms through which scientific knowledge is assessed for international policy. CzechGlobe has been represented in these processes, including the selection of Lenka Suchá as a review editor for the IPCC 7th Assessment Report Working Group II and her role as coordinating lead author in the second IPBES Global Assessment (*Global Change Research Institute, 2025*; *Global Change Research Institute, n.d.*). Such participation shows that Czech environmental science contributes not only observations and papers but also judgement. Assessment work requires the ability to evaluate evidence, compare regions, identify uncertainties, and formulate knowledge in a way that can inform public decisions without becoming political advocacy.

The IPBES connection is especially important because biodiversity and ecosystem services have become central to global environmental science. Climate change is not the only planetary crisis. Species loss, habitat transformation, biotic homogenisation, invasive species, soil degradation, pollinator decline, and ecosystem-function changes all affect the conditions of human life. Czech Academy institutes have contributed to these debates through botany, ecology, soil biology, hydrobiology, and global biodiversity networks. This work carries forward older traditions of field biology and taxonomy, but it is now framed by global questions: how much biodiversity is being lost, where human impacts are strongest, which ecosystems are resilient, and how biodiversity affects carbon storage, productivity, and ecosystem services.

The Institute of Botany of the Czech Academy of Sciences provides one of the most important institutional foundations for these contributions. As the largest botanical research centre in the Czech Republic, it conducts research in plant diversity, vegetation ecology, functional ecology, experimental ecology, mycology, and related areas, while also supporting conservation and environmental assessment (*Institute of Botany, 2022*). Botanical science may seem less dramatic than climate modelling or satellite observation, but it is indispensable to global environmental knowledge. Plants are primary producers, carbon stores, habitat formers, indicators of environmental change, and key elements of cultural landscapes.

Without botanical expertise, biodiversity science becomes abstract and unreliable. The Academy's botanical work therefore gives global environmental science a necessary taxonomic, ecological, and historical depth.

One clear example is the Institute of Botany's participation in international studies of plant diversity across large spatial scales. Research involving Czech botanists has contributed to understanding species richness in small areas, including studies showing that some Eastern European steppe sites can contain exceptionally high plant diversity at fine spatial scales (*Institute of Botany, 2022*). This matters because global biodiversity is often discussed through tropical forests, coral reefs, or charismatic fauna, while temperate grasslands and steppes may receive less attention. Czech and Central European botanical expertise helps correct that imbalance by showing that high biodiversity can occur in small, historically managed, semi-natural landscapes. This contribution is both scientific and cultural: it reminds global environmental science that biodiversity value is not always where public imagination expects it to be.

The PLADIAS database represents another major Czech contribution to global and comparative biodiversity science. It integrates information on Czech flora and vegetation, including species distribution, traits, vegetation types, descriptions, maps, and species composition, and is designed to support research, education, conservation, and environmental assessment (*PLADIAS, n.d.*). Although PLADIAS is nationally focused, its scientific value is broader. Trait databases, vegetation records, and distribution maps allow Czech flora to be compared with other regional floras, used in macroecological analysis, and connected to international biodiversity infrastructures. A well-curated national database can therefore become part of global biodiversity science. It shows how local expertise, when standardised and digitised, becomes internationally usable.

Czech botanical research also contributes to global questions of plant adaptation and climate change. Studies involving researchers from the Institute of Botany have addressed epigenetic memory in clonal plants, forest microclimate mapping, Himalayan alpine shrub growth under global warming, and Arctic tundra plant-community responses to climate change (*Institute of Botany, 2024*; *Institute of Botany, n.d.*; *Biology Centre, 2025*). These examples are important because they show that Czech Academy-related environmental science is not confined to Central Europe. Czech researchers work in mountain systems, Arctic environments, tropical regions, and global comparative networks. Their contribution lies in applying strong ecological, physiological, and statistical expertise to environments where climate change is altering growth, distribution, disturbance, and community dynamics.

The Dendrochronological Laboratory of the Institute of Botany adds another global dimension. Its research focuses on reconstruction of tropical cyclone activity, impacts of climate change on forest growth, detection of forest disturbances, forest dynamics, and forest management (*Institute of Botany, n.d.*). Tree rings are among the most powerful natural archives of environmental history. They allow researchers to reconstruct climate variability, drought, disturbance events, forest growth responses, and long-term ecological change. Czech dendrochronological work therefore contributes to global environmental science by linking biological records with climate history. It also shows how a method rooted in careful measurement of wood anatomy and tree growth can illuminate broad questions of climate change and forest resilience.

The Biology Centre of the Czech Academy of Sciences contributes to global environmental science through ecology, hydrobiology, soil biology, parasitology, entomology, and related fields. Its researchers participate in international studies of biodiversity, aquatic systems, soil carbon, invasive species, and ecosystem responses to climate and human pressure. The Biology Centre's involvement in the DarkDivNet study, for example, linked Czech Academy researchers to a global network examining "dark diversity" — species that could live in a site but are absent — across thousands of vegetation plots in 119 regions (*Biology Centre, 2025*). This approach revealed hidden human impacts that ordinary species counts might miss. The significance of such work is methodological as well as empirical: it changes how biodiversity loss is measured and interpreted.

The Biology Centre's work on soil carbon also has global relevance. Soil is one of the largest terrestrial carbon reservoirs, and its response to plant diversity, land use, climate, and management is crucial for climate mitigation. Research involving Biology Centre scientists has examined why plant diversity can increase soil carbon storage in some contexts but not others, showing that the effect depends on the amount and form of carbon already present in the soil and on ecosystem type (*Biology Centre, 2025*). This kind of work is important because simplistic claims about biodiversity and carbon storage can mislead policy. Czech researchers contribute by clarifying the conditions under which biodiversity supports soil carbon sequestration. Their work therefore links ecology, biogeochemistry, climate policy, and land management.

Aquatic research provides another important Czech contribution. The Biology Centre's Institute of Hydrobiology works on reservoirs, lakes, eutrophication, plankton, microbial loops, fish communities, phosphorus cycling, and long-term aquatic ecosystem processes (*Biology Centre, n.d.*). These themes are globally significant because freshwater ecosystems are among the most pressured environments in the world. Eutrophication, algal blooms, phosphorus accumulation, climate warming, fish-community shifts, and reservoir management affect water quality, biodiversity, public health, recreation, and food systems. Czech reservoir research is especially valuable because reservoirs integrate catchment processes, nutrient loads, management decisions, and climate variability. They are experimental and observational systems where global freshwater problems can be studied in detail.

The FERRO project, involving the Biology Centre as one of seven partners from six European countries, illustrates how Czech hydrobiology participates in European environmental innovation. The project addresses eutrophication in European lakes, with attention to phosphorus, algal blooms, restoration, Earth observation, biochemistry, hydrobiology, plant science, and sonar sediment monitoring (*Biology Centre, 2024*). Its importance lies in the combination of ecological restoration and resource thinking. Phosphorus is both a pollutant in lakes and a finite nutrient resource essential for food production. Czech participation in this project shows how environmental science now has to link ecosystem recovery, circular resource use, remote sensing, and climate-change impacts. This is a genuinely global problem expressed through European freshwater systems.

Czech hydrobiology has also contributed to the digital transformation of conservation science. Biology Centre researchers have led or participated in work on emerging digital tools for marine and freshwater conservation, including culturomics and iEcology, which use digital traces and large-scale online information to support ecological and conservation research (*Biology Centre, 2020*). Such work expands the meaning of environmental data. It suggests that public

attention, digital media, citizen observations, online images, and cultural signals may complement traditional ecological monitoring. This does not replace field science, but it gives conservation researchers new sources for understanding human–nature interactions. Czech contributions here are methodological and interdisciplinary, joining ecology with data science and social observation.

The Academy's contribution to global environmental science also includes atmospheric research and participation in European atmospheric infrastructures. The Institute of Atmospheric Physics maintains long-term observations and works on meteorology, atmospheric dynamics, cloud and precipitation processes, boundary-layer physics, ionospheric research, and near-space phenomena (*Institute of Atmospheric Physics, n.d.*). Its Milešovka observatory, with measurements beginning in 1905, is part of a long tradition of atmospheric observation that now feeds into climate and atmospheric-composition research. Through ACTRIS-CZ and related European cooperation, Czech atmospheric observations become part of wider efforts to standardise and compare data on aerosols, clouds, trace gases, and atmospheric processes (*Institute of Atmospheric Physics, n.d.*; *ACTRIS, n.d.*). This contribution is essential because atmospheric change is spatially distributed and requires coordinated observation.

Space-related environmental science also forms part of the Czech contribution. The boundary between Earth science and space science has become increasingly porous because satellites, solar activity, ionospheric disturbances, geomagnetic storms, and near-Earth objects all affect environmental observation and technological systems. The Institute of Atmospheric Physics has long worked on upper-atmospheric and near-space processes, including participation in satellite missions and solar-wind research (*Institute of Atmospheric Physics, n.d.*). The Astronomical Institute contributes research on solar physics, meteors, interplanetary matter, and the near-Earth space environment (*Astronomical Institute, n.d.*). These fields may seem distant from environmental science in a narrow sense, but they are part of the observational and physical context in which global environmental knowledge is produced. Earth observation itself depends on space technology, and the Earth's atmosphere is influenced by solar and cosmic processes.

Geology and geophysics provide another foundation for global environmental contributions. The Institute of Geology, Institute of Rock Structure and Mechanics, and Institute of Geophysics study geological history, rock environments, geodynamics, seismology, geomagnetism, and the physical structure of the Earth (*Institute of Geology, n.d.*; *Institute of Geophysics, n.d.*; *Institute of Rock Structure and Mechanics, n.d.*). These fields contribute to global environmental science by providing knowledge of deep time, landscape evolution, natural hazards, mineral and rock systems, and the physical stability of the environment. Climate and biodiversity change are often discussed as contemporary issues, but they unfold in landscapes shaped by geological structures and histories. Czech earth-science expertise therefore helps place environmental change within the longer temporal and physical context of the Earth system.

Seismological monitoring and international data exchange show how even a relatively low-seismicity country can contribute to global geophysical science. The Czech Regional Seismological Network and WEBNET record natural and induced seismicity, earthquake swarms, rockbursts, and other seismic events, while contributing to international seismological data systems (*Institute of Geophysics, n.d.*). Such observations help

researchers understand crustal processes, fault systems, induced seismicity, and regional geodynamics. In global environmental science, natural hazards are increasingly studied together with human activity, infrastructure, and risk governance. Czech geophysical expertise therefore belongs to the wider field of environmental risk science, even when its immediate object is the Earth's physical interior.

The Czech Academy's environmental contribution is also institutional and methodological. It helps demonstrate how environmental science can be organised in a small or medium-sized country without losing global relevance. The Academy combines specialised institutes with cross-cutting programmes, long-term monitoring with modern data systems, national databases with international networks, and field expertise with remote sensing and modelling. This institutional pattern is important because global environmental science depends on distributed competence. No single country, no matter how large, can observe all ecosystems, climates, species, soils, waters, or atmospheric processes. The global system depends on many national and regional institutions producing reliable knowledge. The Czech Academy is one such institution, and its contribution is strongest when local expertise is made globally comparable.

The role of long-term observation is especially important in this regard. Global environmental science is increasingly data-rich, but long-term, carefully curated, standardised records remain rare. Mountain observatories, greenhouse-gas stations, ecosystem flux towers, botanical databases, hydrological catchments, reservoir records, seismic networks, and vegetation plots are forms of scientific memory. Czech contributions to global science often come from precisely this memory. They allow researchers to ask whether change is new, how fast it is happening, what baselines are appropriate, and how local processes fit into global trends. The Academy's long-term commitment to observation is therefore one of its most valuable international assets.

The Academy's environmental science also contributes through conceptual caution. Global environmental debates often seek simple narratives: more biodiversity always means more carbon, wetlands always retain more water, forests always cool landscapes, and technological solutions can quickly solve complex environmental problems. Czech Academy research frequently complicates such narratives. Hydrological studies of peatlands and forest soils, biodiversity studies of dark diversity and plant traits, soil-carbon research, eutrophication studies, and climate-risk modelling all show that environmental processes are conditional, scale-dependent, and historically shaped (*Akademie věd České republiky, 2024*; *Biology Centre, 2025*; *Institute of Hydrology, n.d.*). This caution is not scepticism about environmental change. It is a sign of mature science. It makes policy more realistic because it prevents ecological slogans from replacing evidence.

The human dimensions of global environmental change have become increasingly important in Czech Academy research. CzechGlobe includes research on impacts of global change on human society, adaptation, governance, and socio-economic systems (*Global Change Research Institute, n.d.*). This is essential because environmental change is not only biophysical. It affects agriculture, forestry, urban life, infrastructure, migration, health, cultural values, and political decision-making. Conversely, human choices shape land use, emissions, adaptation pathways, and biodiversity outcomes. Czech contributions to global environmental science therefore include not only measurements of atmosphere and ecosystems, but also analysis of how societies understand, govern, and respond to environmental risk.

This social-scientific dimension connects the environmental sciences to the broader institutional history of the Academy. Earlier chapters of this book have shown that the Academy's mission repeatedly shifted in relation to the state, public needs, and scientific autonomy. Environmental science makes this relation especially explicit. Climate and biodiversity knowledge cannot remain enclosed in institutes; it must enter public debate, planning, education, and international assessment. Yet it must do so without losing scientific independence. The Academy's contribution to global environmental science is therefore also a contribution to the democratic culture of expertise. It shows how public research can inform society while resisting both political manipulation and simplistic activism.

International collaboration is not an optional supplement to this work. It is the condition of global environmental science. Czech researchers participate in European infrastructures, Horizon Europe projects, IPCC and IPBES assessments, FLUXNET, ICOS, ACTRIS, biodiversity networks, lake-restoration consortia, Arctic and mountain studies, tropical monitoring, and remote-sensing communities. These collaborations allow Czech science to compare its data, test its methods, and contribute to wider syntheses. They also expose Czech researchers to international standards of openness, reproducibility, data sharing, and peer review. Through these practices, the Academy's environmental institutes become part of a global epistemic community while retaining responsibility for Czech territory and Central European problems.

The educational role of these contributions should also be emphasised. Global environmental science requires researchers capable of working across disciplines, scales, and cultures. The Academy trains young scientists through doctoral supervision, field stations, international projects, ecosystem infrastructures, databases, modelling platforms, and cooperation with universities. A young ecologist, climatologist, hydrologist, botanist, geophysicist, or remote-sensing specialist trained in the Academy's environment learns not only techniques, but also the discipline of long-term observation and international comparison. This human-capital contribution is less visible than a major paper or database, but it is essential for the reproduction of environmental expertise.

Czech contributions to global environmental science also have a cultural dimension. They show that a country's landscapes are not merely domestic scenery; they are part of the planetary system. Czech forests, fields, wetlands, reservoirs, mountain observatories, seismic stations, botanical plots, and urban heat islands can all become sites where global environmental questions are investigated. This changes the meaning of national scientific responsibility. To know one's own territory well is no longer a provincial task. It is part of global environmental knowledge. The Academy's work thus continues the older Czech tradition of linking science with national cultural self-understanding, but it gives that tradition a planetary horizon.

The global environmental contribution of the Czech Academy is therefore not a single achievement or one famous discovery. It is a cumulative pattern of participation: greenhouse-gas measurements, ecosystem flux data, remote-sensing methods, climate-risk portals, IPCC and IPBES expertise, botanical databases, biodiversity syntheses, hydrobiological lake studies, soil-carbon research, atmospheric observations, seismic networks, hydrological monitoring, and interdisciplinary adaptation research. This pattern is typical of environmental science as a whole. Its most important contributions often take the form of networks, datasets, assessments, models, methods, and long-term comparisons rather than isolated

breakthroughs. The Academy's strength is that it can sustain precisely these less spectacular but globally necessary forms of knowledge.

Thus, Czech contributions to global environmental science demonstrate how the Czech Academy of Sciences transformed national expertise into international relevance. Through CzechGlobe, the Institute of Botany, the Biology Centre, the Institute of Atmospheric Physics, the Institute of Hydrology, the Institute of Geophysics, the Institute of Geology, the Institute of Rock Structure and Mechanics, the Astronomical Institute, and their partners, the Academy contributes to climate science, biodiversity research, ecosystem monitoring, atmospheric observation, freshwater restoration, soil-carbon analysis, remote sensing, geological and geophysical knowledge, and global environmental assessments. These contributions are rooted in the landscapes and scientific traditions of the Czech lands, but they now operate within planetary frameworks. They show that a national academy can serve both its own society and the global community by preserving long-term expertise, producing reliable data, participating in international networks, and offering scientifically grounded interpretations of environmental change. In this sense, Czech environmental science is one of the clearest expressions of the modern Academy's wider mission: to make local knowledge part of global responsibility.

Chapter Eleven

Life Sciences, Biomedicine, and Biotechnology

Biology after 1993: Continuity and Renewal

1. Molecular biology, genetics, and cell biology

After 1993, biology within the Academy of Sciences of the Czech Republic entered a period in which continuity and renewal were not opposing tendencies but two sides of the same institutional transformation. The establishment of the Academy of Sciences of the Czech Republic after the dissolution of the Czechoslovak Academy of Sciences did not erase the older scientific schools, laboratory cultures, and disciplinary traditions that had accumulated under Czechoslovak conditions. Yet it placed them within a new political, legal, financial, and international environment. In biological research, this shift was especially visible because molecular biology, genetics, and cell biology were among the fields most strongly affected by global methodological change in the late 20th century. The Academy inherited institutes that had survived ideological control, resource limitations, interrupted international exchange, and the long consequences of normalisation. At the same time, these institutes entered a world in which publication in international journals, competitive grants, peer evaluation, European research programmes, and access to advanced instrumentation became decisive for scientific legitimacy. Biology after 1993 therefore cannot be described simply as a continuation of previous research agendas. It was a reorganisation of Czech biological science around molecular mechanisms, experimental systems, core facilities, and international standards of research performance. The change was not only intellectual but also institutional, because laboratories had to learn new forms of management, funding, collaboration, and scientific communication. The Academy's biological institutes became part of a wider transformation in which the autonomy of science had to be rebuilt not as isolation from the state, but as accountable self-government within a democratic research system. In this sense, molecular biology after 1993 became one of the most visible signs that the post-socialist Academy was not merely preserving inherited expertise, but translating it into a new European language of research (*Academy of Sciences of the Czech Republic, n.d.*; *Czech Academy of Sciences, n.d.*).

The most important background to this transformation was the peculiar strength of Czechoslovak experimental biology before 1989. Unlike some fields that had been more directly subordinated to ideological narratives, experimental biology possessed strong international roots, although these roots were often constrained by political circumstances. Genetics had suffered severely in the Stalinist period, especially under the influence of anti-Mendelian and Lysenkoist doctrines, but Czechoslovak science nevertheless produced important work in immunology, virology, microbiology, plant biology, and experimental medicine. This created a paradoxical inheritance. On the one hand, biological institutes carried the memory of ideological pressure, personal exclusions, and restricted contacts with Western science. On the other hand, they also preserved strong experimental cultures, technical skills, and individual scientific reputations that could be reactivated after the political opening of

1989. The post-1993 Academy thus inherited not a blank institutional landscape, but a dense and uneven map of laboratories, research groups, and scientific lineages. Molecular biology, genetics, and cell biology benefited from this map because they could build on earlier work in immunogenetics, retrovirology, microbial physiology, plant genetics, and developmental biology. The shift after 1993 was therefore not simply from backwardness to modernity. It was a movement from politically constrained excellence to internationally exposed excellence. This distinction is important because it prevents the history of Czech biology from being reduced to a story of Westernisation. The Academy did not merely import molecular biology from abroad; it reconnected older Czechoslovak biological schools with the global molecular revolution that had transformed life sciences since the 1970s and 1980s (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Iványi, 2003*).

The Institute of Molecular Genetics became one of the central institutions through which this continuity was carried into the post-socialist period. Its deeper origins lay in the Department of Experimental Biology and Genetics of the Institute of Biology of the Czechoslovak Academy of Sciences, associated with Milan Hašek and the Czechoslovak immunogenetic school. The foundation of the Institute of Experimental Biology and Genetics in 1962, and its later transformation into the Institute of Molecular Genetics in 1976, signalled that Czech experimental biology had already begun to move towards a molecular interpretation of living systems before the democratic transformation. The work of Hašek and his colleagues belonged to a broader international history of immunological tolerance, transplantation biology, and the study of cellular recognition. Later achievements associated with retrovirology, reverse transcriptase research, virogeny, and viral genome sequencing demonstrated that the institute had not been isolated from some of the major questions of 20th-century biology. Yet this scientific development took place in a political environment that limited mobility, damaged careers, and narrowed participation in international networks. The post-1989 and post-1993 periods therefore gave the institute a new institutional horizon. It could reinterpret its own history not only as a tradition of national excellence, but also as a resource for renewed international competitiveness. The molecular orientation that had emerged under difficult conditions became the basis for a more open, diversified, and technologically intensive research culture. The Institute of Molecular Genetics thus embodied the wider Academy problem of the 1990s: how to preserve accumulated scientific capital while changing almost every condition under which that capital was reproduced. Its later development showed that continuity was most productive when it was not conservative, but adaptive and institutionally self-critical (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Hejnar, 2017*).

The reorganisation of biology after 1993 was shaped by the general legal and institutional framework of the new Academy. The Academy of Sciences of the Czech Republic was not created as a learned society in the old 19th-century sense, nor as a ministry-like command structure inherited from the socialist period. It became a public non-university research organisation, with institutes as its principal research units and with a statutory mission covering natural, technical, social, and human sciences. This mattered for biology because the life sciences required long-term institutional stability, expensive equipment, specialised personnel, and international collaboration. The state remained the principal source of institutional funding, but the political logic of funding changed. Institutes now had to operate within a plural research system in which grant competition, evaluation, external partnerships, and European programmes acquired growing importance. Biological research was particularly

sensitive to this shift because modern molecular and cellular work depends on continually renewed technologies: sequencing platforms, imaging systems, flow cytometry, proteomics, bioinformatics, animal facilities, and controlled plant-growth environments. The Academy therefore had to combine autonomy with infrastructural responsibility. It could not leave each laboratory to survive alone, but it also could not return to a centrally planned distribution of scientific priorities. The post-1993 institutional model encouraged institutes to define their own research profiles while submitting them to periodic assessment and external comparison. This framework gradually changed the internal culture of biological research from one organised primarily around departments and senior scientific authority to one increasingly organised around research groups, project teams, services, and infrastructures (*Czech Academy of Sciences, n.d.*; *Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*).

The transformation was also epistemic. Molecular biology changed what counted as an explanation in the biological sciences. Earlier institutional traditions in physiology, morphology, taxonomy, microbiology, and experimental medicine did not disappear, but they increasingly had to be linked to genes, proteins, signalling pathways, cellular structures, molecular interactions, and genomic information. The living organism was no longer studied only as an anatomical, physiological, ecological, or developmental whole. It was increasingly interpreted as a system of regulated molecular processes operating across scales from DNA and RNA to cells, tissues, organs, populations, and environments. Czech Academy institutes followed this wider international movement, but they did so in a distinctive way because many older research orientations remained institutionally embedded. Plant physiology became plant molecular genetics and plant biotechnology. Microbiology became molecular and cellular microbiology, microbial genomics, host-pathogen interaction, and biotechnology. Experimental medicine became more closely linked with stem cells, tissue engineering, developmental biology, neurobiology, oncology, genetic toxicology, and nanomedicine. Animal physiology and genetics connected biomedical questions with evolutionary, developmental, and biodiversity-oriented approaches. Molecular genetics itself expanded into genomics, bioinformatics, immunology, molecular oncology, mechanobiology, and virology. The result was not the replacement of biology by molecular technique, but the molecularisation of many biological questions. This was one of the most important disciplinary shifts in the Academy's life sciences after 1993 (*Institute of Experimental Botany of the Czech Academy of Sciences, n.d.*; *Institute of Microbiology of the Czech Academy of Sciences, n.d.*; *Institute of Experimental Medicine of the CAS, n.d.*).

At the Institute of Molecular Genetics, the phrase "from genes to function" captures more than a research slogan. It reflects the historical movement from gene-centred analysis to the study of dynamic biological processes in cells, tissues, and organisms. In the post-1993 period, molecular genetics could no longer remain a narrow discipline concerned only with heredity or gene structure. It had to engage with cell signalling, differentiation, development, genome integrity, epigenetic regulation, tumour biology, immune responses, virology, and the molecular basis of disease. This expansion changed the institute's internal organisation. Research groups became increasingly specialised, but their specialisation was embedded in shared technical platforms and conceptual overlaps. Laboratories working on RNA biology, transcriptional regulation, genome dynamics, adaptive immunity, cancer biology, cell motility, tissue morphogenesis, cilia genetics, structural neurobiology, or developmental mechanobiology could be institutionally separate while depending on common

infrastructures. This created a new type of academy institute, less like a collection of disciplinary departments and more like a research ecosystem. The institute's modern profile shows how Czech biological science moved from disciplinary identity to problem-based and technology-enabled organisation. Molecular biology was no longer one field among others; it became a common language through which diverse biological problems could be discussed. Such a language supported international collaboration because it connected Czech laboratories to global research agendas. It also supported institutional renewal because younger scientists could build laboratories around internationally recognisable topics rather than around inherited administrative divisions (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*).

One of the major changes after 1993 was the growing importance of core facilities and shared research infrastructures. In socialist-era institutes, expensive equipment often marked the boundary between privileged and less privileged laboratories, and access could depend on administrative hierarchy or personal networks. In the post-socialist Academy, the logic gradually shifted towards service groups, shared platforms, national infrastructures, and open access to specialised technologies. This development was especially important in molecular biology and cell biology, where individual laboratories rarely possess the full range of necessary equipment. Advanced imaging, electron microscopy, flow cytometry, sequencing, proteomics, bioinformatics, chemical screening, and animal model generation became not merely technical support but part of the epistemic machinery of modern biology. The Institute of Molecular Genetics illustrates this new model through its research services and infrastructures, including Czech-BioImaging, ELIXIR CZ, CZ-OPENSCREEN, and the Czech Centre for Phenogenomics. These infrastructures connected the Academy to broader national and European networks in biological imaging, biological data, chemical biology, and model organism research. They also changed the social organisation of science. Technical specialists, facility managers, data analysts, and service scientists acquired growing importance alongside principal investigators. The modern biological institute therefore became more collective and more infrastructural than the older image of a laboratory centred on a single scientific school. This infrastructural transformation was a key condition for Czech biology's integration into the European Research Area (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*).

The growth of genomics and bioinformatics was among the most consequential changes in Academy biology after 1993. Earlier molecular biology had often been experimental in a relatively focused sense: a gene, a virus, a pathway, a protein, a cell line, or a model organism. By the late 1990s and especially after the completion of major genome projects, biological research increasingly became data-intensive. Sequencing technologies transformed the scale of inquiry. They made it possible to compare genomes, identify regulatory elements, study gene expression, trace evolutionary relationships, analyse pathogens, and connect molecular variation with disease, development, and adaptation. Czech biological institutes had to develop not only wet-lab capacities but also computational expertise. The rise of bioinformatics therefore linked biology to mathematics, computer science, statistics, and information theory. This connection was institutionally important because the Academy already possessed strong traditions in mathematics, cybernetics, informatics, and theoretical modelling. The post-1993 molecularisation of biology thus encouraged interdisciplinary bridges inside the Academy itself. Genomics was not only a new method but also a new institutional language, because it required data storage, software tools, databases,

international standards, and reproducible workflows. Through infrastructures such as ELIXIR CZ and through local genomics and bioinformatics groups, Czech biology participated in a broader European movement towards biological data integration. This development also made biological research more transparent and more dependent on international comparability (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Institute of Experimental Botany of the Czech Academy of Sciences, n.d.*).

Cell biology developed in parallel with molecular genetics, but its significance lay in restoring the living cell as a dynamic spatial system rather than treating it as a passive container for genes. Modern cell biology after 1993 increasingly relied on imaging, cytometry, fluorescent labelling, molecular probes, live-cell observation, ultrastructural analysis, and computational interpretation. This was a decisive change because many biological processes cannot be understood from sequence information alone. Cell division, differentiation, motility, intracellular transport, signal transduction, tissue formation, immune responses, and tumour invasion all require attention to cellular architecture and cellular dynamics. Czech Academy institutes developed these lines of research in several overlapping domains. At the Institute of Molecular Genetics, cell biology connected with cytoskeleton research, cell signalling, cell nucleus biology, cell motility, mechanobiology, developmental processes, and cancer. At the Institute of Experimental Medicine, cellular research was linked with neurobiology, stem cells, tissue replacement, and pathology. At the Institute of Experimental Botany and the Institute of Plant Molecular Biology, cell biology was inseparable from plant development, hormonal regulation, cytogenetics, epigenetics, photosynthesis, plant-virus interactions, and adaptation. This breadth shows that cell biology became a bridge between molecular detail and organismal function. It also made the Academy's biological research more visibly connected to medicine, agriculture, environmental stress, and biotechnology. The cell became one of the privileged sites where fundamental science and social relevance met (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Institute of Experimental Medicine of the CAS, n.d.*; *Institute of Plant Molecular Biology of the Biology Centre CAS, n.d.*).

Plant molecular biology formed another important component of post-1993 biological renewal. Czech plant science had older roots in botany, plant physiology, cytogenetics, agriculture-related research, and experimental botany. After the political transformation, these traditions were increasingly reconfigured through molecular genetics, genomics, biotechnology, cell biology, and environmental stress research. The Institute of Experimental Botany defined its principal research fields around plant genetics, physiology, and biotechnology, including structural and functional genomics, DNA repair, pollen molecular genetics, plant development, growth regulation, plant viruses, and plant pathophysiology. The Institute of Plant Molecular Biology in České Budějovice, founded in 1990 and later incorporated into the Biology Centre CAS, represented a particularly clear example of the transition from genetically oriented teams to a specialised molecular plant research environment. This was not merely a technical shift. Plant molecular biology became increasingly important because agriculture, climate change, environmental pollution, and food security gave plant research new strategic significance. The Academy's work in this area therefore stood between basic biology and long-term societal need. Its value did not depend on immediate technological application alone, but on understanding the mechanisms by which plants develop, respond to stress, regulate growth, and adapt to changing conditions. Post-1993 plant biology thus showed the Academy's ability to preserve fundamental research while making it relevant to sustainability. It also linked Czech biology to European programmes

supporting excellence, international advisory boards, and mobility of researchers. In this respect, plant molecular biology became one of the fields in which the boundaries between molecular science, ecology, agriculture, and global environmental concern became increasingly porous (*Institute of Experimental Botany of the Czech Academy of Sciences, n.d.*; *Institute of Plant Molecular Biology of the Biology Centre CAS, n.d.*; *Academy of Sciences of the Czech Republic, 2023*).

Microbiology after 1993 likewise illustrates the broadening of molecular and cellular approaches. The Institute of Microbiology of the Czech Academy of Sciences, established as an independent institute in the Czechoslovak period, developed into one of the major centres for basic and applied microbiological research. Its research profile covered microbial physiology, molecular and cellular microbiology, immunology, biotechnology, biosynthesis of natural products, environmental and soil microbiology, microbial pathogenesis, gnotobiology, and photosynthetic microorganisms. This breadth is historically important because microbiology connects several scales of biological inquiry. It deals with molecular mechanisms inside microorganisms, with interactions between microbes and hosts, with environmental communities, and with industrial or medical applications. After 1993, these scales became increasingly integrated through molecular methods. The study of bacteria, yeasts, fungi, algae, and mammalian cell lines moved towards regulatory systems, signalling processes, metabolic pathways, genome analysis, and biotechnological exploitation. This made microbiology one of the Academy fields most naturally positioned between basic research and practical use. Yet its institutional significance should not be reduced to application. Microbiology provided a model of how fundamental research on life cycles and molecular mechanisms could generate knowledge relevant to medicine, industry, ecology, and public health. The post-socialist Academy's emphasis on strategic applied research was therefore not foreign to microbiology; it corresponded to the field's own internal structure. In this sense, microbiology helped bridge the inherited Academy tradition of basic science with the democratic state's growing expectation that public research should also contribute to society (*Institute of Microbiology of the Czech Academy of Sciences, n.d.*).

Biomedical molecular biology became more prominent in the Academy's life sciences during the same period. The Institute of Experimental Medicine, founded in 1975, continued after 1993 as a centre for basic biomedical research, with attention to biochemistry, cell and developmental biology, pathology, molecular embryology, genetic toxicology, nanotoxicology, neurobiology, neurophysiology, neuropathology, oncology, tissue replacement, and nanomedicine. Its profile demonstrates that post-1993 biology cannot be separated from medicine even when it remains institutionally outside the university hospital system. The Academy's biomedical institutes did not simply reproduce clinical medicine; they studied mechanisms, models, cells, tissues, and molecular processes underlying disease and regeneration. This distinction mattered because it allowed long-term basic research to support future medical innovation without being subordinated to immediate clinical service. Stem cell research, tissue engineering, neurobiology, and cancer biology required exactly this type of protected but internationally connected environment. They also required ethical regulation, public accountability, and careful communication with society, especially as genetic and cellular technologies became more powerful. The Academy's biomedical biology thus participated in a broader European debate on responsible research. After 1993, the issue was no longer only whether science was free from ideological control. It was also whether science could maintain autonomy while responding to ethical expectations, patient interests, and

public concern. The life sciences made this question particularly visible because their discoveries touched the body, heredity, disease, reproduction, ageing, and human vulnerability (*Institute of Experimental Medicine of the CAS, n.d.*; *ENRIO, 2026*).

The creation of the Institute of Biotechnology of the Czech Academy of Sciences in 2008 marked a further stage in the post-1993 development of molecular biology. This institute belonged to a later institutional generation than the older ČSAV-derived institutes. It reflected the growing importance of biotechnology, structural biology, biomolecular mechanisms, translational potential, and links between basic research and biomedical or veterinary applications. Its establishment showed that the Academy's biological structure was not frozen by the early post-socialist transformation. New institutes and centres could still be created when scientific and strategic circumstances required them. The Institute of Biotechnology developed within the environment of BIOCEV, the biotechnology and biomedicine centre associated with the Academy and Charles University. This was significant because it represented a more networked model of institution-building. Rather than treating Academy institutes and universities as separate worlds, BIOCEV embodied the logic of shared infrastructure, interdisciplinary research, and regional scientific clustering near Prague. In the context of molecular biology, such centres were essential because modern research required critical mass, expensive equipment, and close interaction between biology, chemistry, medicine, informatics, and technology transfer. The Institute of Biotechnology therefore symbolised a later phase of Academy renewal: not only the survival and reform of inherited institutes, but the creation of new platforms for competitive biomedical and molecular research. It also strengthened the Academy's position in the emerging economy of knowledge transfer without abandoning the primacy of excellent basic science (*Institute of Biotechnology of the Czech Academy of Sciences, n.d.*).

BIOCEV itself represented one of the most important institutional innovations in Czech life sciences after 1993. Its significance lay not only in buildings, laboratories, or equipment, but in the kind of research culture it promoted. The centre linked Academy institutes with Charles University, concentrated expertise in biotechnology and biomedicine, and created conditions for collaboration across institutional boundaries. Such centres reflected the impact of European structural funds and the broader policy idea that research excellence could be strengthened through modern infrastructure and regional concentration. For molecular biology and cell biology, this was particularly important because the scale of equipment and the speed of methodological change made isolated laboratories less viable. BIOCEV also contributed to changing the geography of Czech science. The traditional Prague academic environment remained central, but new campuses and research complexes in Vestec and elsewhere created a more distributed map of scientific capacity. This had implications for doctoral training, international recruitment, interdisciplinary projects, and cooperation with industry. In the Academy's history, such centres also marked a departure from the older model of institutes as self-contained entities. They encouraged a layered structure in which institutes retained identity but shared facilities, projects, and strategic orientations. This model was especially suitable for molecular life sciences, where the same imaging platform, animal facility, sequencing service, or structural biology equipment may serve many research questions. The post-1993 Academy thus moved from institutional preservation to infrastructural integration (*Institute of Biotechnology of the Czech Academy of Sciences, n.d.*; *Institute of Microbiology of the Czech Academy of Sciences, n.d.*).

Generational renewal was another essential feature of molecular biology, genetics, and cell biology after 1993. The opening of borders changed the biography of Czech scientists. Younger researchers could undertake doctoral or postdoctoral work abroad, participate in international conferences, publish more regularly in English, and join European research networks. Senior scientists who had maintained contacts despite political restrictions could renew older connections, while younger scientists could build careers in a more mobile academic world. This mobility had ambivalent consequences. On the one hand, it created risks of brain drain, especially in the 1990s when Czech salaries and research infrastructure often lagged behind Western standards. On the other hand, it produced circulation of knowledge, methods, and laboratory practices. Scientists returning from abroad, or maintaining dual collaborations, helped to introduce new experimental standards and management habits. English became increasingly important not merely as a publication language but as a daily language of seminars, grant proposals, international recruitment, and laboratory communication. The Academy's institutes therefore became more open social spaces than they had been during normalisation. Their internal cultures gradually changed from nationally bounded academic communities to multilingual and internationally networked environments. This change was crucial in molecular biology because access to cutting-edge methods often travels through people before it is stabilised in equipment. The renewal of Czech biology was therefore as much a renewal of scientific careers and laboratory sociability as it was a renewal of institutional statutes (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*).

The role of doctoral education also changed. Although the Academy did not become a university, its institutes increasingly participated in doctoral training through cooperation with universities. This cooperation was particularly important in molecular biology, genetics, and cell biology because doctoral students require access to advanced laboratories, model systems, equipment, and internationally visible research topics. The Academy's role in doctoral education helped bridge the old institutional division between university teaching and academy research. During the socialist period, this division had often been rigid, with the Academy functioning as a powerful research sector and universities bearing the primary burden of education. After 1993, cooperation became more necessary and more productive. University students entered Academy laboratories; Academy scientists supervised or co-supervised doctoral research; joint centres created more integrated training environments. This had consequences for the reproduction of scientific elites. Young biologists no longer inherited a closed institute culture; they entered a competitive and networked field where career progression depended on publications, grants, international experience, and technical competence. In this sense, the molecular life sciences became one of the fields in which the Academy's modernisation and the university system's reform overlapped most strongly. Doctoral education also helped connect Czech research to European standards of training, mentoring, mobility, and evaluation. The Academy's biological institutes thus became both research organisations and formative environments for the next generation of Czech and international scientists (*Czech Academy of Sciences, n.d.*; *Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*).

Research evaluation and competitive funding reshaped the internal life of biological institutes. In molecular biology and cell biology, evaluation could not rely only on institutional prestige or historical reputation. It increasingly depended on publications in international journals, citation impact, grants, patents, infrastructure use, international cooperation, and participation in European projects. This created pressure, but it also offered opportunities.

Laboratories that could formulate strong research questions and connect them to international debates were able to compete for resources beyond the basic institutional budget. The changing funding environment encouraged project-based organisation, strategic planning, and professional grant administration. It also altered the relationship between seniority and authority. Older scientific prestige remained important, but younger group leaders with international publications and grant success could gain institutional visibility more rapidly than in the past. At the same time, evaluation introduced tensions familiar across European science: pressure to publish, dependence on metrics, administrative burden, and the risk that short-term grant cycles might weaken long-term exploratory research. The Academy's challenge was to use evaluation as a tool of renewal without allowing it to destroy the patient temporality that fundamental biology often requires. Molecular biology is fast-moving in method, but many biological questions require years of cumulative experimentation. The post-1993 Academy therefore had to balance speed and continuity, competition and institutional memory, international standards and local scientific cultures (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *ENRIO, 2026*).

Internationalisation was not only a matter of travel or publication. It changed the substance of research questions. Czech molecular biologists increasingly participated in projects where problems were defined at a European or global scale: cancer biology, immune regulation, developmental mechanisms, host-pathogen interactions, genome stability, plant adaptation, biodiversity genomics, biological imaging, chemical biology, and biological data infrastructures. This meant that national science became less provincial not because it abandoned national institutions, but because those institutions became nodes in transnational networks. The Academy's biological institutes retained Czech historical identities, Czech public funding, and Czech educational responsibilities. Yet their scientific legitimacy increasingly depended on their ability to contribute to research conversations that were not bounded by national borders. This was especially true in genomics and cell biology, where data, standards, protocols, and equipment are inherently international. A sequencing result, an imaging dataset, a cell line, or a mouse model becomes valuable when it can be interpreted and reproduced within a wider scientific community. The Academy therefore had to cultivate compatibility: methodological compatibility, ethical compatibility, data compatibility, and institutional compatibility. This did not make national research traditions irrelevant. Rather, it allowed Czech biological schools to speak in a language that others could recognise. The post-1993 renewal of biology was thus a process of translation between inherited expertise and global scientific infrastructures (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Czech Academy of Sciences, n.d.*).

The relationship between basic and applied research became increasingly nuanced in the life sciences. The older Academy tradition had often defended basic science as a protected space of long-term knowledge production, and this defence remained necessary after 1993. However, molecular biology, genetics, and cell biology made the boundary between basic and applied research more permeable. A study of signalling pathways could inform cancer research. Work on genome integrity could become relevant to ageing, disease, or toxicology. Plant molecular genetics could support breeding, agriculture, and adaptation to environmental stress. Microbial physiology could lead to biotechnology, natural products, or medical applications. Chemical biology infrastructures could identify molecular probes and drug candidates. Yet these applied possibilities depended precisely on the strength of basic research. The Academy's biological institutes therefore operated within a model of "strategic

basic research", even when this phrase was not always used explicitly. They pursued fundamental mechanisms while remaining attentive to medicine, industry, agriculture, environment, and public health. This model suited the post-socialist Czech state, which increasingly expected public research to contribute to competitiveness and societal problem-solving. It also suited the internal logic of modern biology, where mechanistic knowledge often becomes applicable unpredictably. The history of Academy biology after 1993 therefore shows that innovation does not arise by replacing basic research with applied projects, but by creating institutional conditions in which deep biological knowledge can move towards application when the time is right (*Institute of Biotechnology of the Czech Academy of Sciences, n.d.*; *Institute of Microbiology of the Czech Academy of Sciences, n.d.*; *Institute of Experimental Botany of the Czech Academy of Sciences, n.d.*).

The post-1993 development of biological research also strengthened the importance of scientific integrity and ethical governance. Molecular genetics, biomedical research, animal models, stem cells, genetic toxicology, human-related samples, and data-intensive biology all raise questions that go beyond laboratory technique. They require rules for responsible conduct, reproducibility, authorship, data management, animal welfare, human health relevance, and public communication. The Academy's democratic transformation therefore had an ethical dimension. Freedom from political ideology did not mean freedom from norms. On the contrary, the credibility of autonomous science depended on transparent standards of good scientific practice. The Commission for Scientific Integrity of the Czech Academy of Sciences, established in the early 2000s, reflected this broader institutional shift. In the life sciences, such frameworks were especially important because errors, misconduct, or irresponsible communication could have consequences for medicine, environment, and public trust. Molecular biology's authority rests partly on its technical power, but that power must be socially accountable. The Academy had to cultivate a culture in which scientific ambition was disciplined by ethical responsibility. This was another difference from the socialist past: the problem was no longer ideological conformity, but professional integrity in a competitive, international, and publicly visible research environment. Biological research after 1993 thus became part of the Academy's broader movement from controlled science to responsible science (*ENRIO, 2026*; *Czech Academy of Sciences, n.d.*).

The history of Czech molecular biology after 1993 also reveals how institutional memory can be used constructively. The Academy's biological institutes did not simply celebrate their predecessors; they reinterpreted them. Milan Hašek, Jan Svoboda, Václav Pačes, and other figures from Czechoslovak experimental biology became part of a narrative in which Czech science had contributed to international developments despite political adversity. Such narratives mattered for institutional identity. They gave younger scientists a sense that they were not working in a peripheral or derivative environment. They also helped institutes explain their mission to the public, to policymakers, and to international partners. Yet memory could not substitute for contemporary excellence. The post-1993 Academy had to show that historical achievement could be followed by current research quality. The strongest institutes were those able to connect legacy with renewal: to preserve names, schools, and themes while changing methods, evaluation standards, and organisational forms. This balance was particularly visible at the Institute of Molecular Genetics, whose history from immunogenetics and retrovirology to genomics and cell biology made continuity itself a dynamic concept. The past was not a museum of achievements; it was a reservoir of scientific confidence. In the broader institutional history of the Academy, this ability to transform memory into future-

oriented research was one of the most important signs of successful modernisation (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Iványi, 2003*; *Weiss, 2018*).

The biological institutes of the Academy also participated in the broader redefinition of Czech science's public image. During the socialist period, science was often publicly represented as a state achievement, tied to industrial modernity, planned development, and ideological progress. After 1993, the public legitimacy of science had to be reconstructed in a democratic, media-oriented, and increasingly European society. Biology played a major role in this reconstruction because it dealt with themes that citizens could understand as directly relevant: health, cancer, infectious disease, environment, food, agriculture, biodiversity, ageing, and biotechnology. At the same time, molecular biology could appear abstract, expensive, and technically opaque. The Academy therefore had to communicate not only results but also the value of long-term fundamental research. Public outreach, institutional websites, science festivals, popularisation activities, and media communication became increasingly important. The life sciences were well suited to this public role because images of cells, plants, microbes, embryos, tissues, and model organisms can make invisible processes visible. Yet communication also carried risks of simplification and excessive promises. The Academy's task was to show that molecular biology matters without turning every discovery into immediate medical or commercial salvation. This required a more mature public language of science than the old rhetoric of progress. In this sense, biological research after 1993 contributed to a new civic understanding of the Academy as a public institution producing knowledge, expertise, and long-term capacity for society (*Czech Academy of Sciences, n.d.*; *Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*).

The regional dimension of biological research should not be underestimated. Prague remained a major centre, especially through the Krč campus, Dejvice traditions, Charles University connections, and later the Vestec/BIOCEV environment. However, Academy biology was not limited to Prague. České Budějovice became especially important through the Biology Centre CAS and its institutes in entomology, hydrobiology, parasitology, plant molecular biology, and soil biology. The inclusion of plant molecular biology within this wider biological and ecological environment encouraged connections between molecular mechanisms and ecological questions. This regional distribution mattered because it prevented the post-1993 Academy from becoming a purely metropolitan institution. It also linked biological research to local ecosystems, field stations, environmental monitoring, agricultural landscapes, and regional universities. In life sciences, place is not simply an administrative fact. Laboratories depend on campuses and infrastructures, but ecological and evolutionary research also depends on landscapes, species, water systems, soils, and long-term observation. Even molecular biology can benefit from proximity to ecological and organismal research because genes and cells ultimately operate in organisms and environments. The Czech Academy's biological geography therefore supported a layered research culture, from molecules in Prague and Vestec to plants, parasites, insects, soils, and waters in South Bohemia and beyond. This geography will become even more visible in discussions of ecology, evolutionary biology, and biodiversity, but it already mattered for molecular biology because modern life science increasingly moves across scales (*Biology Centre CAS, n.d.*; *Institute of Plant Molecular Biology of the Biology Centre CAS, n.d.*).

The post-1993 transformation also changed the relation between biological research and academic elites. Under socialism, scientific elites were shaped by a combination of intellectual authority, party politics, institutional hierarchy, and access to resources. After

1989, legitimacy had to be reconstructed through scientific reputation, democratic governance, international recognition, and managerial competence. In molecular biology, this created new forms of leadership. A successful institute director or group leader had to understand not only the science itself, but also grant strategy, international recruitment, infrastructure planning, intellectual property, ethical rules, and communication with the Academy leadership and state authorities. The rise of research groups placed more responsibility on principal investigators. At the same time, the increasing complexity of biology made leadership more distributed. Facility heads, data specialists, project managers, doctoral supervisors, and international advisory boards all became part of scientific governance. This did not eliminate hierarchy, but it changed its basis. Authority depended less on administrative seniority alone and more on the ability to sustain a productive research environment. The Academy's biological institutes thus became laboratories not only of molecular processes but also of new institutional forms. Their internal evolution reflected the broader post-socialist movement from bureaucratic control to accountable, performance-oriented, and internationally visible research leadership (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Czech Academy of Sciences, n.d.*).

The international reputation of Czech molecular and cellular biology after 1993 cannot be understood only through institutional reform. It also depended on specific scientific achievements and the ability of Czech laboratories to contribute to global debates. Some achievements built directly on older traditions, such as retrovirology, immunology, plant genetics, and microbial research. Others emerged from newer infrastructures and collaborations. The move into genomics, imaging, phenogenomics, structural biology, biotechnology, and molecular medicine allowed Czech researchers to participate in research areas where international visibility depends on both conceptual contribution and technical capacity. This was a demanding transition. It required investment, but also a change in scientific ambition. Laboratories could no longer be satisfied with national recognition or regional relevance. They had to frame their questions in a way that mattered to international communities. The Academy's strength lay in giving some of these laboratories the stable institutional base needed for ambitious research. Unlike short-term project organisations, Academy institutes could maintain expertise, equipment, collections, models, and long-term research programmes across decades. This stability was especially valuable in biology, where cumulative work on model systems, organisms, pathways, and technologies often produces results slowly. The post-1993 story of biological research is therefore not a simple triumph of competition over institutional continuity. It is a story of how competition became productive when anchored in durable institutions capable of sustaining research depth (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Institute of Microbiology of the Czech Academy of Sciences, n.d.*).

The COVID-19 pandemic, although belonging to a later phase of the period, revealed the strategic importance of molecular biology and genetics for the state and society. The pandemic made visible to the public what had long been true inside laboratories: molecular detection, sequencing, bioinformatics, virology, immunology, and biomedical infrastructures are not luxuries but components of national resilience. Czech scientific institutions participated in testing, genomic surveillance, data interpretation, and expert communication. This experience should not be read narrowly as a public health episode. It demonstrated the long-term value of investment in molecular life sciences. Laboratories trained in molecular techniques could respond to a crisis because they had accumulated personnel, equipment, protocols, and

collaborative habits before the crisis arrived. The pandemic also showed that the boundary between fundamental research and emergency application can collapse rapidly. A scientist studying viral genomes, immune responses, or molecular diagnostics may suddenly become part of a national response system. For the Academy, this reinforced the argument that public research institutions must maintain capacities that are not always immediately profitable or politically visible. Biological research after 1993 thus acquired a new form of public legitimacy in the 21st century. It was no longer only a matter of excellence and publication, but of preparedness, expertise, and the ability to mobilise knowledge under conditions of uncertainty (*Šúri et al., 2025*).

The development of molecular biology, genetics, and cell biology after 1993 also complicates the distinction between national and European science. Czech Academy institutes remained national institutions, funded largely by the Czech public sector and embedded in Czech legal structures. Yet their everyday scientific life became increasingly European. They participated in European infrastructures, Horizon programmes, mobility schemes, advisory boards, collaborative projects, and common standards of research assessment. This Europeanisation did not mean the loss of national identity. Instead, it made national research more capable of acting beyond the national frame. The Academy's biological institutes could represent Czech science internationally precisely because they were institutionally stable at home. European integration also encouraged comparison with other small and medium-sized research systems. Czech biology had to ask how a country of limited size could sustain excellence in expensive fields. The answer lay in specialisation, infrastructure sharing, international recruitment, cooperation with universities, and selective concentration of resources. Molecular biology after 1993 therefore became part of the broader European problem of how to organise excellence outside the largest scientific powers. The Academy's experience shows that institutional continuity, if combined with reform, can give smaller systems a durable place in global science. This was one of the most important lessons of the post-socialist transformation (*Czech Academy of Sciences, n.d.*; *Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Institute of Biotechnology of the Czech Academy of Sciences, n.d.*).

The history of this field also reveals the changing relationship between science and innovation policy. In the 1990s, the immediate task was survival and reform: preserving institutes, renewing personnel, re-establishing international contacts, and adapting to democratic governance. By the 2000s and 2010s, the language of innovation, competitiveness, technology transfer, and applied impact became more prominent. Molecular biology was naturally drawn into this language because its discoveries could lead to diagnostics, therapeutics, biotechnology, agricultural tools, or industrial processes. However, the Academy's biological institutes had to resist a simplified innovation narrative that measures value only through quick commercialisation. Many life-science discoveries become useful only after long periods of basic research, replication, refinement, and collaboration. The institute model allowed such long horizons to survive. Technology transfer, commercial licences, cooperation with companies, and applied projects were important, but they worked best when grounded in high-quality fundamental science. The Academy's biological research therefore illustrates a mature understanding of innovation: not a linear pipeline from laboratory to market, but a complex ecology of knowledge, skills, infrastructures, public funding, and unpredictable discovery. This ecology was one of the major achievements of the post-1993 transformation. It allowed the Academy to speak to policymakers about societal benefit without abandoning the intellectual autonomy on which its strongest contributions depended (*Institute of Molecular Genetics of*

the Czech Academy of Sciences, n.d.; *Institute of Biotechnology of the Czech Academy of Sciences, n.d.*).

By the 2020s, molecular biology, genetics, and cell biology had become deeply embedded in the Academy's self-understanding as a modern research organisation. The field showed how the Academy could combine historical depth with methodological modernity. It drew on Czechoslovak schools of immunogenetics, retrovirology, microbiology, plant research, and experimental medicine, but it operated through research groups, infrastructures, European networks, international publications, doctoral training, and ethical frameworks. Its development also showed that post-socialist transformation was not a single event completed in the early 1990s. It was a long process of institutional learning. Laboratories had to learn to compete, cooperate, publish, evaluate, internationalise, communicate, and innovate under changing conditions. The Academy leadership had to learn how to support expensive research without recreating centralised control. The Czech state had to learn that public research institutions require autonomy, stability, and accountability at the same time. Biology made all these lessons visible because it was one of the most rapidly changing and resource-intensive areas of science. Its history after 1993 is therefore a key chapter in the broader institutional history of the Academy. It shows how a post-socialist research organisation could become part of contemporary European science without dissolving its own institutional memory. It also shows that the renewal of science depends not only on laws and budgets, but on laboratories, people, instruments, standards, and narratives of purpose.

Thus, molecular biology, genetics, and cell biology after 1993 became one of the clearest expressions of the Czech Academy's transformation from a post-socialist successor institution into a modern European research organisation. The field preserved important Czechoslovak scientific lineages, especially in immunogenetics, virology, microbiology, plant biology, and experimental medicine, but it reworked them through molecular methods, cell-based analysis, genomics, bioinformatics, imaging, research infrastructures, and competitive international collaboration. Its development demonstrates the central tension of the post-1993 Academy: scientific autonomy had to be defended, but autonomy now required accountability, evaluation, ethical standards, cooperation with universities, and openness to society. Biological research showed that continuity is strongest when it is capable of renewal, and that institutional memory becomes historically productive only when it supports new questions, new generations, and new forms of scientific organisation. In this sense, the post-1993 history of molecular biology within the Academy is not a specialised disciplinary episode, but a condensed example of the whole Academy's modernisation.

2. Ecology, Evolutionary Biology, and Biodiversity

After 1993, ecology, evolutionary biology, and biodiversity research within the Academy of Sciences of the Czech Republic developed under conditions rather different from those that shaped molecular biology and cell biology. These fields were not driven only by laboratories, instruments, or molecular platforms, although they increasingly used them. They also depended on landscapes, long-term observation, collections, field stations, taxonomic expertise, experimental plots, animal populations, forests, rivers, ponds, soils, wetlands, and historical memory of the natural environment. This gave them a particular institutional character. They carried forward older Czechoslovak traditions of botany, zoology, hydrobiology, entomology, parasitology, soil biology, vegetation science, and nature

conservation. At the same time, they had to respond to a new global agenda in which biodiversity loss, climate change, biological invasions, ecosystem services, habitat fragmentation, and environmental policy became central scientific and political questions. The post-socialist transformation therefore did not simply modernise these fields by making them more international or more technologically advanced. It also changed their public meaning. Ecology was no longer a specialised biological discipline concerned only with organisms and environments; it became a form of long-term national expertise and a bridge between science, conservation, agriculture, forestry, water management, climate policy, and public responsibility. Evolutionary biology, meanwhile, gained new strength from genetics, genomics, phylogeography, mathematical modelling, and comparative methods. Biodiversity research became both an empirical science and a political necessity, because the Czech state, the European Union, and global organisations increasingly required reliable knowledge about species, habitats, ecological change, and conservation priorities (*Biology Centre CAS, n.d.*; *Institute of Botany of the Czech Academy of Sciences, n.d.*).

The continuity of ecological and evolutionary research after 1993 was rooted in the older structure of Czechoslovak biological science. Unlike some areas of the humanities and social sciences, ecology was not always politically central, but it was never politically neutral either. The socialist state needed knowledge of forests, soils, water, agriculture, pests, fisheries, and landscape management. At the same time, environmental damage under state socialism created urgent questions that could not be solved by ideological declarations. Pollution, industrial agriculture, acidification, forest decline, river regulation, wetland transformation, and habitat degradation all placed ecological knowledge in a difficult position. Scientists had to produce expertise for a state that was often responsible for the very damage they were studying. After 1989 and 1993, this relationship changed. Ecological knowledge could be more openly connected with public criticism, environmental legislation, conservation, and international environmental debates. The Academy's ecological institutes therefore entered the democratic period with both scientific capital and moral relevance. They were not merely preserving collections or continuing field surveys; they were helping Czech society understand the environmental consequences of the previous century. The renewal of ecological biology after 1993 was therefore also part of the wider civic transformation after the Velvet Revolution. It made nature, landscape, and biodiversity part of the Academy's broader public mission (*Czech Academy of Sciences, n.d.*; *Institute of Botany of the Czech Academy of Sciences, n.d.*).

The Institute of Botany became one of the central institutions in this post-1993 ecological landscape. Its roots go back to the Geobotanical Laboratory of the biological institutions of the Czechoslovak Academy of Sciences in the 1950s and to the foundation of the Institute of Botany in the early 1960s. The location at Průhonice Castle and the connection with the park and botanical garden gave the institute an unusual symbolic profile, linking modern research with cultivated landscape, historical garden culture, and Central European botanical tradition. After 1993, this inheritance did not become antiquarian. The institute continued to work on taxonomy, biosystematics, plant evolution, ecology, ecophysiology, phytogeography, vegetation mapping, dendrochronology, palaeoecology, karyology, and population genetics. This breadth is important because it shows that ecological and biodiversity research were not reduced to one fashionable topic. They required the coexistence of classical taxonomy, field botany, long-term vegetation science, experimental methods, spatial analysis, and molecular tools. The institute also preserved the importance of expert knowledge that cannot be generated quickly by short-term projects. A vegetation scientist, taxonomist, lichenologist,

mycologist, or palaeoecologist needs years of accumulated experience, local knowledge, and familiarity with collections and landscapes. In this respect, the Institute of Botany defended a form of scientific continuity that was essential for biodiversity science. Without such continuity, biodiversity would become an abstract policy slogan rather than a precisely documented reality (*Institute of Botany of the Czech Academy of Sciences, n.d.*; *Chytrý, 2012*).

The Czech lands have always offered a particularly rich setting for vegetation research because they lie at a biogeographical crossroads. The country contains lowlands, uplands, mountain systems, river valleys, wetlands, forest-steppe fragments, karst areas, sandstone landscapes, glacial cirques, serpentine habitats, anthropogenic grasslands, ponds, forests, agricultural mosaics, and urban ecosystems. This diversity made Czech vegetation science unusually sensitive to history and spatial pattern. The present landscape cannot be understood without the last glacial period, Holocene forest development, medieval settlement, agriculture, grazing, forestry, industrialisation, collectivisation, and post-socialist land-use change. After 1993, this historical dimension became even more important because conservation policy required not only lists of species but also knowledge of how communities had formed and how they were changing. Vegetation ecology therefore linked natural history with human history. It asked how plant communities responded to management, abandonment, eutrophication, drainage, succession, invasion, climate shifts, and fragmentation. In this sense, ecology within the Academy had a cultural dimension as well as a biological one. It studied nature not as an untouched realm separate from society, but as a layered landscape produced by long interactions between climate, organisms, geology, land use, and political economy. This perspective fitted the broader institutional history of the Academy, where science repeatedly stood at the boundary between national knowledge and universal research (*Chytrý, 2012*; *Institute of Botany of the Czech Academy of Sciences, n.d.*).

The post-1993 period also strengthened the relationship between ecology and data. Traditional field observation remained essential, but it was increasingly organised through databases, georeferenced records, digital maps, statistical modelling, remote sensing, and open-access platforms. The Czech botanical and vegetation tradition was especially well suited to this transformation because it had accumulated large quantities of floristic and phytosociological information over many decades. Projects such as national vegetation classification, distribution mapping, and plant trait databases turned this accumulated knowledge into modern research infrastructure. The development of the Pladias database of the Czech flora and vegetation is particularly significant in this respect. It shows how biodiversity expertise moved from printed floras and local inventories into dynamic digital systems that combine occurrence records, traits, ecological indicators, distribution maps, threat categories, and taxonomic information. Such databases changed the scale of ecological research. They allowed scientists to ask broader questions about plant distribution, habitat preferences, invasions, climate sensitivity, conservation status, and functional ecology. They also made ecological knowledge more accessible to conservation agencies, students, policymakers, and international partners. This was a major institutional change because it transformed biodiversity knowledge into a shared public and scientific resource. The Academy's contribution to such data systems strengthened its role as a long-term custodian of national natural knowledge (*Danihelka et al., 2021*; *Institute of Botany of the Czech Academy of Sciences, n.d.*).

Evolutionary plant biology became one of the fields in which classical botany and modern evolutionary science most visibly converged. The study of plant diversity was no longer limited

to description, classification, and distribution. It increasingly asked how species originate, how genomes change, how polyploid complexes evolve, how hybridisation shapes plant lineages, how ecological differentiation appears among closely related taxa, and how microevolutionary processes operate at the population level. The Department of Evolutionary Plant Biology at the Institute of Botany illustrates this shift through its focus on genome processes, horizontal gene transfer, DNA endoreduplication, cytogenetics, phylogeography, diploid-polyploid complexes, hybrid speciation, molecular systematics, and broader evolutionary forces. These themes show that post-1993 evolutionary biology was neither purely molecular nor purely field-based. It required herbarium work, field sampling, cytogenetic analysis, molecular data, ecological interpretation, and comparative thinking. It also required an institutional environment where long-term organismal expertise could interact with newer genetic methods. This interaction was historically important because it prevented the separation of “old” natural history from “new” molecular biology. In Czech Academy botany, taxonomy and evolution remained connected. This connection gave biodiversity research greater explanatory power, because species were studied not only as names in a catalogue but as dynamic evolutionary entities. The result was a more integrated biology, capable of moving from chromosome and genome to population, species, community, and landscape (*Institute of Botany of the Czech Academy of Sciences, n.d.*).

Invasion ecology became another internationally visible part of Czech post-1993 ecological research. Biological invasions were a particularly suitable theme for a transformed Europe because they linked globalisation, trade, agriculture, urbanisation, landscape disturbance, conservation, and environmental risk. Czech researchers, especially those associated with the Institute of Botany, contributed substantially to the study of alien plants, invasiveness, habitat invasibility, impact assessment, and global databases of naturalised alien floras. This field was important institutionally because it combined basic ecological theory with practical relevance. It asked why some species become invasive while others do not, why some habitats are more vulnerable than others, and how the impacts of alien species should be classified and managed. After 1993, such questions gained importance because Czech conservation policy became increasingly linked to European directives, international conventions, and global biodiversity debates. Invasion ecology also helped Czech science become more visible internationally because the problem was inherently transnational. Alien species do not respect political borders, and their study requires comparative datasets across countries and continents. The Academy’s strength lay in combining Central European field knowledge with global conceptual frameworks. This made invasion ecology a model case of how a small country’s research community could influence an international field by producing high-quality data, concepts, and classification tools (*Institute of Botany of the Czech Academy of Sciences, n.d.*; *Pyšek et al., 2020*).

The Biology Centre CAS in České Budějovice became one of the most important institutional innovations in the ecological and biodiversity sciences after 1993. Created in 2006 by the Czech Academy of Sciences, it brought together five institutes: Entomology, Hydrobiology, Parasitology, Plant Molecular Biology, and Soil Biology and Biogeochemistry. This structure itself expresses a distinctive understanding of biology. It does not divide life simply into plants, animals, microbes, and molecules. Instead, it concentrates on interactions: insects and plants, hosts and parasites, aquatic communities and water quality, soil organisms and biogeochemical cycles, plant genomes and environmental adaptation. The Biology Centre’s location in South Bohemia also mattered. It connected research to the University of South

Bohemia, to pond landscapes, wetlands, forests, agricultural environments, and the wider Central European ecological setting. It made České Budějovice a major centre of biological research rather than a peripheral regional site. In the institutional history of the Academy, the Biology Centre shows how post-1993 reform could create new organisational forms without abandoning older scientific traditions. It gathered inherited institutes and research groups into a larger centre capable of competing internationally and supporting interdisciplinary work. This was renewal by integration rather than renewal by demolition (*Biology Centre CAS, n.d.*).

The Institute of Entomology illustrates especially well the combination of continuity, specialisation, and international expansion. Founded within the Czechoslovak Academy of Sciences in 1962, it inherited earlier work in entomology and insect pathology. Its research after 1993 continued to cover taxonomy, genetics, physiology, molecular biology, ecology, insect development, biorhythms, biodiversity, population genetics, molecular evolution, and ecosystem functioning. This breadth is not accidental. Insects are the most species-rich group of animals and are central to pollination, herbivory, decomposition, food webs, pest dynamics, disease transmission, and biodiversity monitoring. An institute devoted to insects therefore stands at the crossroads of fundamental biology and practical concerns. Its older applied work in pest control, pheromones, juvenile hormone analogues, biological agents, agriculture, and forestry did not disappear. Rather, it was complemented by evolutionary ecology, molecular approaches, tropical biodiversity studies, and ecosystem-level analysis. After 1993, the institute became part of an increasingly global entomology, while still retaining Central European expertise. Its role in maintaining research connected with Papua New Guinea shows how a Czech Academy institute could extend far beyond the Czech landscape without losing its institutional base at home. Entomology thus became one of the Academy's strongest examples of biodiversity science as both local and global (*Biology Centre CAS, 2013*; *Academy of Sciences of the Czech Republic, 2022*).

The work of Vojtěch Novotný and his colleagues in Papua New Guinea is particularly revealing for the history of post-1993 Czech ecology. It demonstrates that the transformation of Czech science was not only a return to Europe but also an opening towards global field science. Long-term ecological research in tropical rainforests required much more than occasional expeditions. It required local partnerships, field stations, trained collaborators, trust with Indigenous communities, logistical resilience, and sustained funding. The Binatang Research Centre became a rare example of a research base that connected Czech ecology with one of the richest biodiversity regions on Earth. This work contributed to debates about tropical insect diversity, plant-herbivore interactions, elevational gradients, rainforest ecology, and the global estimation of species richness. It also showed that high-quality ecological research could be conducted through long-term cooperation rather than extractive scientific tourism. In institutional terms, this mattered because it expanded the imagined geography of the Czech Academy. A national academy based in Central Europe could become a serious actor in tropical biodiversity science. The result was not a loss of national scientific identity, but its enlargement. Czech ecology became global by building durable scientific relationships in places where biodiversity itself posed questions that Central Europe alone could not answer (*Academy of Sciences of the Czech Republic, 2022*; *Novotný & Toko, 2015*).

Hydrobiology and aquatic ecology formed another major strand of post-1993 biodiversity research. Czech lands possess a historically dense network of ponds, reservoirs, rivers, wetlands, and managed aquatic landscapes. South Bohemia in particular has long been associated with fishponds, wetland systems, and water-management traditions. After 1993,

these older regional realities acquired new scientific significance because water ecosystems became central to debates about eutrophication, climate change, invasive species, fisheries, ecosystem functioning, and biodiversity conservation. The Institute of Hydrobiology within the Biology Centre contributed to this field by combining limnology, fish ecology, microbial processes, trophic interactions, and modern tracking or modelling techniques. The rise of movement ecology shows how aquatic research became increasingly data-intensive. Animal tracking technologies, telemetry, high-resolution spatial data, and international data-sharing networks made it possible to study fish movement and behaviour at scales that earlier field biology could not reach. Such research linked ecology with informatics, engineering, statistics, and management. It also showed how biodiversity science could become predictive rather than merely descriptive. For the Academy, hydrobiology strengthened the long-term role of scientific expertise in water policy and ecosystem management. It connected field biology with one of the most strategic environmental issues of the 21st century: the future of freshwater systems (*Biology Centre CAS, 2022*).

Soil biology and biogeochemistry added another layer to the Academy's ecological profile. Soil is one of the least visible but most fundamental components of biodiversity. It contains microorganisms, fungi, invertebrates, roots, organic matter, nutrient cycles, and complex interactions that support terrestrial ecosystems and agriculture. Under state socialism, soil was often treated primarily as a productive agricultural resource, subject to intensification and chemical management. After 1993, soil biology could be placed more explicitly within biodiversity, ecosystem functioning, sustainability, and climate debates. The Institute of Soil Biology and Biogeochemistry, as part of the Biology Centre, worked within this wider shift. Its scientific importance lay in making visible the hidden biological systems beneath the surface of landscapes. Soil research linked ecological theory with agriculture, forestry, carbon cycling, restoration, and environmental monitoring. It also required a strongly interdisciplinary approach, because soil processes involve organisms, chemistry, hydrology, climate, plant communities, and land use. In the broader institutional history of the Academy, soil biology demonstrates how life sciences contributed to a more integrated understanding of the environment. Biodiversity was no longer only what could be seen, counted, photographed, or mapped above ground. It also included subterranean systems whose disturbance could transform whole ecosystems (*Biology Centre CAS, n.d.*).

The Institute of Vertebrate Biology represented a further important centre of ecological and evolutionary research. Its work on vertebrates connected field zoology, evolutionary ecology, population biology, behavioural research, genetics, medical zoology, and biodiversity. The institute's development after 1993 also illustrates the reorganisation of scientific elites and research sites outside Prague. Associated with Brno and Studenec, it contributed to the decentralised geography of Academy biology. Its research on wild-derived mouse strains is a particularly striking example of the connection between ecology, evolution, genetics, and biomedical relevance. Wild-derived strains preserve genetic variation that standard laboratory strains cannot fully represent. They allow scientists to study speciation, hybrid sterility, genome conflict, adaptation, and the evolutionary basis of reproductive isolation. This work shows how evolutionary biology after 1993 moved across boundaries that older disciplinary classifications would have kept separate. A mouse could be an ecological organism, an evolutionary model, a genetic resource, and a biomedical tool at the same time. The Institute of Vertebrate Biology therefore contributed to a wider transformation in which organismal biology became methodologically modern without losing its field-based foundations. Its work

also demonstrated that evolutionary biology could generate knowledge relevant to medicine without becoming subordinate to medical application (*Academy of Sciences of the Czech Republic, n.d.*).

The Institute of Animal Physiology and Genetics also belongs to this wider ecology-evolution-biodiversity constellation. Its profile explicitly combines physiology, genetics, ecology, and evolution, and it studies domestic, wild, and laboratory animals across topics ranging from biomedical models to biodiversity-oriented research. This combination is historically significant because it resists a narrow division between animal production, laboratory biology, and wildlife biology. The institute's work on physiological functions, genetic structures, genome interactions, animal-environment relations, model species, protected species, livestock, food quality, and safety reveals how post-1993 animal biology connected basic research with medicine, ecology, and agriculture. It also shows how inherited research traditions in farm-animal reproduction and physiology could be reinterpreted in a modern Academy context. The institute did not remain locked in an agricultural or veterinary framework. It became part of broader biological questions concerning adaptation, reproduction, development, genome function, and species survival under changing environmental conditions. In this sense, it bridged older state-oriented practical biology and newer evolutionary and ecological biology. Its development also reflects the Academy's broader capacity to renew specialised institutes by expanding their conceptual scope. Animal biology after 1993 thus moved from production-centred expertise towards integrative organismal science (*Institute of Animal Physiology and Genetics CAS, n.d.*).

Parasitology deserves special attention because it links biodiversity, evolution, ecology, medicine, and global change in a particularly direct way. Parasites are not marginal organisms; they are central components of ecosystems, evolutionary pressures, food webs, and disease dynamics. The Institute of Parasitology within the Biology Centre continued a strong Czechoslovak tradition while developing within a more international and interdisciplinary environment after 1993. Parasitological research is important for institutional history because it shows that biodiversity includes forms of life that public culture may perceive negatively or invisibly. Parasites reveal the intimacy of ecological relationships: host specificity, coevolution, immune response, transmission, vector ecology, environmental change, and emerging diseases. After 1993, such research became increasingly relevant because globalisation, climate change, land-use alteration, animal movement, and human mobility all affected parasite distributions and disease risk. Parasitology also created links between Czech Academy biology and tropical research, veterinary science, public health, molecular biology, and evolutionary theory. It therefore resisted any simple distinction between pure and applied research. Like microbiology and entomology, it showed that fundamental knowledge of organisms and life cycles can become crucial when society faces new risks. In the Academy's post-socialist development, parasitology contributed to the transition from national biological expertise to globally relevant life science (*Biology Centre CAS, n.d.*).

Ecology after 1993 was also transformed by climate change. Earlier ecological research had certainly studied environmental gradients, disturbance, succession, and long-term change, but the 21st century placed these questions within a planetary framework. Climate change altered the meaning of local ecological data. A long-term record from a Czech forest, wetland, meadow, pond, or mountain slope could now contribute to understanding global processes. The Institute of Botany's work on microclimate, species distribution modelling, forest disturbances, plant community responses to global change, and remote sensing reflects this

shift. Ecology became more predictive, more spatially explicit, and more closely linked to modelling. It also became more urgent. Scientists were no longer describing stable communities; they were studying systems under pressure. This changed the relationship between ecological research and public policy. Conservation could no longer be based only on preserving selected sites in their existing condition, because climate change itself was altering the ecological conditions under which species and habitats persisted. Czech ecological biology therefore had to connect long-term field knowledge with scenarios, risk assessment, and adaptive management. This was a new form of expertise, suited to an age in which the natural baseline itself was becoming unstable (*Institute of Botany of the Czech Academy of Sciences, n.d.*).

Biodiversity research also became closely connected with the problem of biological invasions and the uncertainty of ecological impact. Invasive species are historically revealing because they expose the ecological consequences of mobility, commerce, colonial histories, horticulture, agriculture, fisheries, forestry, and accidental transport. They are not simply natural phenomena; they are biological signatures of human movement. Czech Academy researchers participated in international work showing how difficult it can be to predict the consequences of alien species introductions. Some species remain apparently harmless for long periods, while others become transformative only under specific ecological conditions. The concept of crypticity in invasions is important because it shows that ecological damage may be delayed, hidden, or misread. This has major implications for management and conservation, since late detection often makes control more difficult. After 1993, Czech invasion ecology became part of a global conversation about uncertainty, risk, and precaution. This field also strengthened the Academy's role in policy-relevant science. It showed that biodiversity expertise is not only about documenting rare species; it is also about understanding dynamic processes that can reorganise ecosystems. Invasion ecology thus connected the Czech Academy to one of the most practical and theoretically challenging areas of contemporary ecology (*Biology Centre CAS, 2019*; *Pyšek et al., 2020*).

The public and political role of biodiversity science expanded significantly in the post-1993 period. The Czech Republic joined international agreements, adapted to European Union environmental frameworks, and participated in broader debates about nature conservation and ecosystem services. Academy researchers were increasingly expected to provide expertise not only for academic journals but also for ministries, conservation agencies, environmental assessments, public debates, and international platforms. The election of Petr Petřík from the Institute of Botany to the Multidisciplinary Expert Panel of IPBES in 2026 is a telling sign of this development. It demonstrates that Czech ecological expertise had become visible within global science-policy structures. IPBES matters because it translates biodiversity research into assessments that influence conservation priorities and political decisions. Participation in such bodies does not mean that science becomes politics. Rather, it means that science must learn to communicate uncertainty, evidence, and long-term ecological knowledge in forms usable by decision-makers. For the Academy, this created a new mode of public responsibility. Ecologists and biodiversity researchers were not merely observers of nature; they became mediators between ecosystems, data, public policy, and society. This role strengthened the Academy's position as a national centre of long-term expertise with international reach (*Institute of Botany of the Czech Academy of Sciences, 2026*).

Taxonomy remained a foundational discipline in this new environment, even though it often received less public attention than genetics, climate science, or conservation policy. The

importance of taxonomy lies in a simple but profound fact: biodiversity cannot be protected, monitored, or understood if organisms cannot be identified, described, and classified. The post-1993 Academy therefore had to maintain taxonomic competence at a time when some research systems were tempted to treat it as old-fashioned. In reality, taxonomy became more important, not less, because biodiversity crisis and global change created urgent demands for reliable species knowledge. The Institute of Botany's emphasis on plant diversity, fungi, lichens, systematics, monographs, phylogenetic relationships, reproductive systems, microevolution, and genome-size variation shows how taxonomy itself was modernised. It was no longer only descriptive morphology. It incorporated molecular systematics, cytogenetics, ecological differentiation, distribution data, and evolutionary interpretation. The same applies to entomology, parasitology, and vertebrate biology, where species identification and systematics remain indispensable. Taxonomy also has a cultural dimension in the Czech context because natural history was historically connected with national education, museums, field clubs, and the mapping of the homeland. After 1993, this older civic tradition was incorporated into a modern biodiversity science that served both national and global needs (*Institute of Botany of the Czech Academy of Sciences, n.d.*; *Biology Centre CAS, 2013*).

Long-term monitoring became one of the Academy's most valuable contributions to ecological knowledge. Many environmental processes become visible only across decades: vegetation change, forest disturbance, wetland dynamics, pond eutrophication, species decline, invasion spread, climate-driven range shifts, soil degradation, and changes in animal movement. Short grant cycles are poorly suited to such processes. Academy institutes, by contrast, have the institutional durability needed to sustain monitoring, collections, field sites, and long-term data series. This is one of the strongest arguments for the Academy model in the ecological sciences. Universities, ministries, and private consultancies all contribute to environmental knowledge, but a public academy can preserve scientific continuity beyond immediate administrative demands. After 1993, this capacity became even more important because environmental change accelerated and policy required evidence. Long-term monitoring also connected generations of scientists. Data collected by one generation could become analytically powerful for the next, especially when combined with digital tools, modelling, and international comparison. In ecology, institutional memory is not merely symbolic; it is often embedded in datasets, plots, collections, and field protocols. The Czech Academy's ecological institutes therefore preserved not only knowledge about the past but also the conditions for understanding future change (*Institute of Botany of the Czech Academy of Sciences, n.d.*; *Biology Centre CAS, n.d.*).

The relationship between ecology and molecular biology became increasingly close after 1993. Earlier disciplinary boundaries had often separated field naturalists from laboratory biologists. In the post-socialist period, that separation gradually weakened. Population genetics, molecular ecology, environmental DNA, genomics, phylogeography, microbiome research, molecular systematics, and evolutionary developmental perspectives gave ecologists new tools. At the same time, field systems gave molecular biologists access to natural variation, adaptation, speciation, and ecological realism. This mutual exchange was especially visible in evolutionary plant biology, vertebrate biology, animal physiology and genetics, entomology, parasitology, and soil biology. It changed the meaning of biodiversity research. Biodiversity was no longer only the number of species in a place; it included genetic variation, functional traits, interactions, evolutionary history, and ecological processes. This shift also encouraged collaboration across Academy institutes. Molecular biologists, botanists, zoologists,

microbiologists, bioinformaticians, and modellers increasingly worked on overlapping questions. The Academy's structure, with multiple specialised institutes under one institutional umbrella, made such connections possible, though not automatic. The development of ecology after 1993 therefore belongs to the same broader transformation as molecular biology: both fields became more interdisciplinary, infrastructural, and internationally comparable (*Institute of Botany of the Czech Academy of Sciences, n.d.*; *Institute of Animal Physiology and Genetics CAS, n.d.*).

The European Union framework changed the conditions under which ecological and biodiversity research operated. After the Czech Republic's accession to the EU in 2004, environmental legislation, conservation directives, research funding, infrastructure policy, and cross-border cooperation became increasingly important. Natura 2000, habitat assessment, water policy, invasive species regulation, climate adaptation, and biodiversity strategies all required reliable scientific expertise. Academy institutes were well positioned to contribute because they combined fundamental research with long-term national knowledge. European research programmes also encouraged collaboration beyond national borders. Czech ecologists worked with partners in Germany, Austria, Slovakia, Poland, France, the United Kingdom, Scandinavia, and many other regions. These collaborations changed the scale of Czech ecological research. Central European data could be compared with pan-European datasets; local questions could be placed within continental gradients; Czech field sites could become part of international networks. At the same time, Europeanisation created pressures: competition for grants, administrative demands, project-based funding, and the need to publish in high-impact international journals. The Academy's ecological institutes had to balance these demands with the slower work of taxonomy, monitoring, collections, and regional expertise. Their success depended on making long-term local knowledge legible within European science (*Czech Academy of Sciences, n.d.*; *Institute of Botany of the Czech Academy of Sciences, 2026*).

The social meaning of ecology also changed after 1993 because Czech society itself became more environmentally conscious. The environmental damage of the late socialist period had been one of the moral and political arguments against the old regime. In the democratic period, environmental issues became part of civil society, education, media, local activism, and public debate. Academy ecologists worked in this environment, even when their primary task remained research. Their expertise could support conservation conflicts, land-use debates, restoration projects, water management, forest policy, agricultural questions, and invasive species control. This created a delicate position. Scientists had to maintain analytical independence while engaging with public concerns. They had to distinguish evidence from advocacy, but they could not pretend that ecological knowledge had no social implications. The Academy's authority depended on exactly this balance. It was trusted not because it was politically silent, but because it could provide long-term evidence and careful interpretation. Ecology thus became one of the fields in which the Academy's democratic public role was most visible. It showed that scientific autonomy after 1993 meant the capacity to speak responsibly within society, not withdrawal from society (*Biology Centre CAS, 2019*; *Institute of Botany of the Czech Academy of Sciences, n.d.*).

The geographic structure of Academy ecological research contributed to the decentralisation of Czech science. Prague remained important, but ecology could not be concentrated only in the capital. Průhonice, Brno, Třeboň, České Budějovice, Studenec, Liběchov, and other sites formed a distributed research landscape. This distribution reflected the logic of the disciplines

themselves. Botanists needed gardens, parks, herbaria, field sites, wetlands, and regional vegetation gradients. Hydrobiologists needed ponds, reservoirs, and water systems. Entomologists and tropical ecologists needed field stations and collections. Vertebrate biologists needed animal facilities and natural populations. Soil biologists needed experimental and natural landscapes. The Academy's ecology therefore had a spatial form very different from that of a purely laboratory-centred science. It was embedded in places. This embeddedness strengthened the Academy's national role because it connected research to the Czech territory in a literal sense. At the same time, these places were not provincial. They became nodes in international networks, hosting conferences, training doctoral students, contributing to European projects, and producing globally relevant research. The post-1993 Academy thus demonstrated that decentralised scientific geography could be a strength rather than a weakness (*Biology Centre CAS, n.d.*; *Institute of Botany of the Czech Academy of Sciences, n.d.*).

Ecology, evolutionary biology, and biodiversity research also contributed to the renewal of academic generations. Field sciences depend strongly on mentorship, because many skills cannot be learned only from textbooks or databases. Species recognition, field sampling, experimental design, ecological judgement, taxonomic caution, and interpretation of landscapes require apprenticeship. After 1993, this traditional mode of transmission was combined with new expectations: international mobility, English-language publication, grant competition, statistical competence, molecular methods, remote sensing, and data management. Young Czech ecologists therefore entered a hybrid professional world. They had to be at once field researchers, analysts, international collaborators, and often public communicators. Academy institutes provided an important environment for this training, especially through cooperation with universities and doctoral programmes. The Biology Centre's connection with the University of South Bohemia and the Institute of Botany's links with universities in Prague, Brno, and elsewhere helped integrate research and education. This was institutionally significant because it softened the older divide between Academy research and university teaching. It also ensured that specialised ecological knowledge did not remain confined to ageing expert communities. Generational renewal was essential for the survival of taxonomy, field ecology, and biodiversity monitoring, all of which are vulnerable when expertise is not deliberately transmitted (*Biology Centre CAS, n.d.*; *Institute of Botany of the Czech Academy of Sciences, n.d.*).

The rise of big data changed ecology in ways comparable to the transformation of genetics by genomics. Movement ecology provides a particularly clear example. Earlier animal movement studies were constrained by the difficulty of observing animals across long periods and large areas. New technologies such as GPS, radar, telemetry, computer vision, and automated detection systems made it possible to collect high-resolution data on movement, behaviour, habitat use, and interaction. Czech researchers from the Biology Centre participated in international work on this big-data revolution and in initiatives involving lake fish telemetry. Such work illustrates the new methodological profile of ecology after 1993. Field biology did not disappear; it became instrumented, digital, collaborative, and computational. The resulting datasets required advanced statistics, interoperability, data sharing, and international standardisation. This pushed ecology closer to informatics and systems science. It also opened new possibilities for conservation and management, because movement data can reveal migration corridors, habitat fragmentation, behavioural responses, and species vulnerability. For the Academy, this transformation strengthened the argument that ecological

research must be supported as advanced science, not treated as a low-technology remnant of natural history (*Biology Centre CAS, 2022*).

Global biodiversity research also forced Czech scientists to confront inequalities within science itself. Participation in tropical, conservation, and global ecological studies raised questions about who produces data, who receives authorship, who controls research agendas, and how local expertise is recognised. Recent work involving researchers from the Biology Centre has drawn attention to persistent geographical disparities in global ecology and conservation science. This issue is historically important because post-1993 Czech science itself had experienced a transition from semi-peripheral status to European integration. Czech researchers understood the importance of visibility, partnership, and access to networks. In global biodiversity research, similar problems appear on a wider scale. Scientists from biodiversity-rich but economically marginalised regions may contribute essential knowledge while remaining underrepresented in publications and decision-making. A mature ecological science cannot ignore this imbalance. The Academy's involvement in such debates shows that biodiversity research is not only about organisms and ecosystems; it is also about the social organisation of scientific knowledge. This represents a further stage in the Academy's internationalisation. Czech ecology did not merely join global networks; it also began to reflect critically on how those networks function (*Biology Centre CAS, 2025*).

The relation between biodiversity and culture became another emerging dimension of ecological research. Conservation is not only a biological problem, because human values, memory, aesthetics, livelihoods, local identities, and public imagination shape how societies respond to nature loss. Academy-related discussions on biodiversity conservation and the arts point to a broader recognition that ecological crisis cannot be solved by data alone. This does not diminish the importance of rigorous science. Rather, it acknowledges that evidence must enter social worlds where decisions are made through emotion, politics, economics, education, and cultural meaning. In the Czech context, this point has particular resonance because landscape has long been connected with national culture, literature, local identity, tourism, and historical memory. The Academy's ecological research therefore indirectly contributed to cultural self-understanding. It helped society see meadows, forests, ponds, wetlands, insects, fungi, and plant communities not as decorative backgrounds but as living systems with histories and futures. Such a perspective fits the wider narrative of the Academy's institutional history. The Academy was never only a producer of technical knowledge; it was also a national institution shaping the way society understood itself and its place in the world. Biodiversity research after 1993 continued this role under the conditions of environmental crisis (*Biology Centre CAS, 2025*; *Institute of Botany of the Czech Academy of Sciences, n.d.*).

The development of ecology and biodiversity research after 1993 also reveals a specific form of scientific autonomy. In molecular biology, autonomy often depended on equipment, funding, peer review, and international laboratory standards. In ecology, autonomy also depended on the ability to maintain inconvenient truths about environmental change. Ecological research may show that land-use practices are damaging, that conservation policies are insufficient, that invasive species are underestimated, that forests are vulnerable, that water systems are stressed, or that agricultural landscapes are losing biodiversity. Such findings can conflict with economic interests or political comfort. A democratic Academy must therefore protect ecological expertise even when it complicates policy. At the same time, autonomy cannot mean isolation from practice. Ecologists must work with conservation authorities, ministries, land managers, municipalities, farmers, foresters, and international

bodies. This creates a productive tension between independence and engagement. The post-1993 Academy's ecological institutes operated within this tension and helped define what responsible public science meant in a democratic state. They showed that autonomy is not the absence of social relevance, but the freedom to produce reliable knowledge for society even when that knowledge is difficult (*Czech Academy of Sciences, n.d.*; *Institute of Botany of the Czech Academy of Sciences, 2026*).

By the 2020s, ecology, evolutionary biology, and biodiversity had become central to the Academy's identity as a long-term research institution. They were no longer peripheral fields beside molecular biology or applied biomedicine. They addressed some of the most urgent questions facing Czech society and the world: climate change, biodiversity loss, invasive species, freshwater vulnerability, soil degradation, forest disturbance, species extinction, ecological monitoring, and the future of conservation. Their institutional strength came from a combination of old and new elements. The old elements included field stations, taxonomic traditions, collections, botanical and zoological expertise, long-term observation, and knowledge of Czech landscapes. The new elements included molecular ecology, databases, remote sensing, modelling, telemetry, global collaborations, European policy frameworks, and science-policy platforms. This combination made the Academy's ecological research particularly valuable. It could speak to local conservation problems while contributing to global theoretical and practical debates. It also demonstrated that the modernisation of science does not always mean replacing older forms of knowledge. Sometimes modernisation means preserving them under new conditions, connecting them to new methods, and giving them renewed public significance. In this sense, ecology and biodiversity research after 1993 became a profound example of continuity transformed into renewal.

Thus, ecology, evolutionary biology, and biodiversity research after 1993 show that the Academy of Sciences of the Czech Republic did not modernise biology only by moving towards molecules, genomes, and biomedical platforms. It also renewed the organismal, field-based, environmental, and evolutionary traditions that had long been part of Czech and Czechoslovak science. The Institute of Botany, the Biology Centre CAS, the Institute of Vertebrate Biology, the Institute of Animal Physiology and Genetics, and related research groups preserved deep expertise in plants, animals, insects, parasites, soils, waters, vegetation, and landscapes, while integrating this expertise with modern data systems, molecular tools, modelling, remote sensing, European research networks, and global conservation agendas. These fields made the Academy a guardian of long-term ecological memory and a participant in contemporary debates about biodiversity crisis, climate change, invasive species, ecosystem services, and science-policy responsibility. Their history demonstrates that institutional continuity can be creative when it is open to methodological renewal and public accountability. It also shows that the Academy's post-1993 transformation was not only a matter of governance and funding, but a redefinition of how Czech science understood life, nature, landscape, and its responsibility to society.

3. Biological Research in European and Global Networks

After 1993, biological research in the Academy of Sciences of the Czech Republic was transformed not only by new methods, institutes, and funding rules, but also by a profound change in its scientific geography. Czech biology ceased to operate within the semi-closed space inherited from the late socialist research system and gradually became embedded in

European and global networks of knowledge production. This did not mean that national institutions lost their significance. On the contrary, the Academy's institutes became more important precisely because they provided the stable institutional bases from which Czech researchers could enter international consortia, European infrastructures, global field projects, and competitive grant systems. The post-1993 history of Academy biology is therefore also a history of scientific networking. Molecular biologists, ecologists, botanists, parasitologists, microbiologists, plant scientists, cell biologists, and evolutionary researchers increasingly worked in environments where research questions, data standards, equipment, publications, doctoral training, and evaluation were transnational. Internationalisation was not a decorative addition to Czech science, nor simply a matter of travelling abroad after decades of restriction. It became one of the basic conditions under which scientific authority was produced. A laboratory, institute, or research group could be nationally funded and institutionally Czech, but its credibility increasingly depended on whether it could speak the methodological and conceptual language of European and global science. This development was especially important in biology, because the life sciences after the late 20th century became highly dependent on shared infrastructures, international databases, model organisms, comparative field sites, global biodiversity data, and cross-border responses to health and environmental risks. In this sense, biological research after 1993 reveals how the Academy entered the European Research Area not as an abstract policy framework, but as a daily reality of laboratories, datasets, conferences, review panels, doctoral mobility, and collaborative publications (*European Commission, 2026*; *Czech Academy of Sciences, n.d.*).

The break with the pre-1989 order should not be exaggerated into a simple story of isolation followed by openness. Czechoslovak biologists had maintained important international contacts even under socialism, although these contacts were uneven, politically filtered, and often dependent on individual courage or institutional privilege. Some scientists travelled, published abroad, corresponded with foreign colleagues, and participated in international debates in virology, immunology, botany, microbiology, parasitology, and ecology. Yet the system as a whole limited mobility, restricted access to equipment and literature, and made international collaboration vulnerable to political judgement. After 1989 and especially after the formation of the Czech Academy in 1993, internationalisation acquired a different institutional meaning. It was no longer an exception granted to selected individuals; it became a strategic expectation for institutes. This change affected the everyday practice of science. English became the dominant language of publication, seminars, grant writing, and project administration. International peer review became a key mechanism of legitimacy. Research careers increasingly required postdoctoral mobility, international co-authorship, and participation in grant competitions beyond the national system. The Academy's biological institutes had to learn how to operate in this new world without losing their inherited strengths. The problem was not simply to "catch up" with Western Europe, but to translate the experience of Czech and Czechoslovak biological schools into a research environment governed by openness, competition, and transnational standards (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Leydesdorff, Wagner, Park, & Adams, 2013*).

The European Research Area became one of the major frameworks through which this transformation was articulated. For Czech biology, the European Research Area was not merely a Brussels policy phrase; it affected grant opportunities, research assessment, mobility schemes, doctoral training, infrastructure planning, data standards, and institutional self-presentation. The Czech Republic's accession to the European Union in 2004 intensified this

process, but it had begun earlier through Framework Programmes, bilateral collaborations, and the post-1989 reintegration of Czech science into European organisations. The Academy had to position itself within a system where excellence, mobility, knowledge circulation, and access to shared infrastructure were repeatedly emphasised as European goals. The establishment of a dedicated European Research Area Section within the Academy's international cooperation structures illustrates how seriously CAS treated this policy environment. Biology was one of the fields most directly affected by it because its contemporary forms require equipment and data systems that individual national institutions cannot easily sustain alone. The Europeanisation of Czech biological research therefore involved both intellectual integration and institutional adaptation. Institutes had to develop project departments, support offices, international advisory mechanisms, and professional grant management. This changed the internal sociology of the Academy. Research was still done by scientists, but successful international science increasingly depended on administrators, project officers, data stewards, technology-transfer specialists, and infrastructure managers. In this sense, the European Research Area helped transform the Academy from a collection of national research institutes into a more networked and professionally managed research organisation (*Czech Academy of Sciences, n.d.*; *European Commission, 2026*).

Framework Programmes, Horizon 2020, Horizon Europe, ERC grants, Interreg, and structural funds created new opportunities, but also new disciplines of institutional behaviour. Biological institutes had to formulate projects in ways legible to international panels. They had to demonstrate excellence, feasibility, impact, training capacity, gender and ethics awareness, data-management plans, and sometimes innovation potential. These requirements could feel bureaucratic, but they also pushed the institutes into stronger strategic thinking. The Biology Centre CAS explicitly benefited from programmes including Interreg, Horizon Europe, and ERC, and its project department became part of the institutional machinery through which ecological, evolutionary, molecular, and biomedical projects could be supported. The same logic applied to Prague-based molecular and biomedical institutes, which increasingly operated through international consortia and shared research infrastructures. Competitive European funding did not replace national support, but it reshaped what national support meant. Stable institutional funding became the platform from which researchers could compete internationally, not a substitute for international competition. This was a major change from the socialist research model, where state allocation had often defined the horizon of institutional possibility. After 1993, the Academy's biological institutes had to operate in a mixed economy of institutional resources, national grants, European projects, infrastructure funding, and collaborative networks. Their success depended on combining scientific imagination with administrative competence (*Biology Centre CAS, n.d.*; *Czech Academy of Sciences, n.d.*).

The European Research Council had particular symbolic value because it represented individual scientific ambition judged by international excellence rather than institutional loyalty or national distribution. For Czech Academy biology, ERC success mattered not only because of money, but because it signalled that Czech laboratories could compete in the most demanding European arenas. ERC projects encouraged high-risk, conceptually ambitious research, and they helped attract or retain talented researchers in Czech institutes. The Biology Centre's presence among CAS institutes with ERC achievements is therefore historically meaningful. It shows that post-1993 biological research did not remain confined to rebuilding

basic capacity; it reached a stage where some groups could define frontier questions on equal terms with leading European laboratories. ERC culture also changed expectations inside institutes. Young group leaders began to imagine careers organised around ambitious international proposals, not only around slow advancement within inherited institutional hierarchies. This did not eliminate inequalities between older and newer member states of the European Union, nor did it solve all problems of salaries, infrastructure, or administrative load. Yet it created a visible route by which scientific excellence could be recognised beyond national boundaries. In the institutional history of the Academy, ERC grants became part of a broader redefinition of prestige: from prestige conferred by position to prestige demonstrated through international peer competition (*Czech Academy of Sciences, 2026*; *European Research Council, n.d.*).

Large research infrastructures became perhaps the clearest material expression of biological internationalisation. Modern biology is not sustained only by brilliant individuals or strong institutes; it also requires platforms that provide services across institutions and national borders. ELIXIR CZ, Czech-BioImaging, CZ-OPENSCREEN, and the Czech Centre for Phenogenomics demonstrate how Academy biology entered this infrastructural age. ELIXIR CZ positioned Czech life science within the European landscape of biological data, bioinformatics tools, specialised databases, storage, and computational capacities. Czech-BioImaging connected Academy institutes, universities, and specialised facilities in a distributed infrastructure for biological and biomedical imaging. CZ-OPENSCREEN provided open access to chemical biology and genetics tools, linking cell biology, molecular biology, structural biology, biochemistry, organic chemistry, and chemoinformatics. The Czech Centre for Phenogenomics, hosted by the Institute of Molecular Genetics, integrated genetic engineering in mice and rats, phenotyping, imaging, metabolomics, data analysis, animal facilities, cryopreservation, and preclinical services at the BIOCEV campus. These infrastructures changed the meaning of collaboration. Cooperation was no longer only a personal relationship between scientists; it became a technical and institutional system through which users could access equipment, expertise, data, protocols, and training. The Academy's biological institutes thus became both producers of research and providers of national and European scientific capacity (*ELIXIR CZ, n.d.*; *Czech-BioImaging, n.d.*; *CZ-OPENSCREEN, n.d.*; *INFRAFRONTIER, n.d.*).

ELIXIR CZ illustrates the new centrality of data in biological networks. In earlier decades, collaboration often meant sharing specimens, letters, reprints, field observations, or laboratory protocols. In contemporary biology, it increasingly means sharing datasets, computational workflows, metadata standards, databases, storage capacities, and analytical tools. This transformation affected molecular biology, genomics, ecology, plant science, microbiology, and biomedical research. Biological data became too large, complex, and valuable to remain inside individual laboratories. Czech participation in ELIXIR therefore had institutional significance beyond bioinformatics as a technical service. It placed Czech life science within a European regime of data interoperability, open science, FAIR principles, and reproducible research. Such systems made Czech biological results more visible and reusable, but they also imposed new standards of documentation, curation, and responsibility. Data became part of the Academy's public and international accountability. For ecology and biodiversity, this shift complemented national databases of flora, vegetation, species distribution, and environmental observations. For molecular biology, it connected sequencing, expression profiles, protein data, phenotyping, and disease-related information.

ELIXIR CZ thus linked the Academy's biological research to one of the defining features of 21st-century science: the transformation of knowledge into networked, standardised, and computationally accessible data (*ELIXIR CZ, n.d.*; *Antol, Marek, Capandová, Juráček, & Matyska, 2024*).

Bioimaging offers another example of how infrastructures created new scientific networks. The Czech-BioImaging network included facilities at the Institute of Molecular Genetics, Institute of Physiology, Institute of Experimental Medicine, Institute of Experimental Botany, Charles University, Masaryk University, Palacký University, Brno University of Technology, the Institute of Scientific Instruments, and the Biology Centre. Such a network reveals the institutional ecology of contemporary biology. No single institute could cover all imaging needs, from light microscopy and electron microscopy to medical imaging, image analysis, and specialised biophysical instrumentation. By connecting facilities across Prague, Brno, Olomouc, České Budějovice, and other sites, Czech-BioImaging created a distributed national capacity with European relevance. This changed the geography of Czech life science. Excellence was not concentrated only in one campus or one institute; it was organised through nodes, services, training, and shared standards. Imaging also created conceptual bridges between molecular biology, cell biology, developmental biology, neuroscience, plant science, microbiology, parasitology, and biomedical research. The image became a scientific object that could move between disciplines. It made cellular and organismal processes visible, measurable, and comparable. Czech-BioImaging therefore helped transform biological observation from an individual laboratory practice into a networked infrastructure of seeing (*Czech-BioImaging, n.d.*).

CZ-OPENSCREEN represents the chemical-biology dimension of this same transformation. Its mission to identify molecular probes and develop tools for research on chemical compounds connected Czech biology with early-stage therapeutic exploration, molecular mechanisms, and interdisciplinary drug-discovery environments. For the Academy, this was important because it linked basic research to potential application without reducing the life sciences to commercial product development. Chemical probes can illuminate biological processes, reveal pathways, validate targets, and create opportunities for biomedical innovation. Yet they depend on highly organised screening capacity, compound libraries, assay development, informatics, and collaboration between chemists and biologists. CZ-OPENSCREEN therefore demonstrates how post-1993 biological research moved into a zone where disciplinary boundaries became increasingly porous. Molecular biologists, cell biologists, structural biologists, biochemists, organic chemists, and computational specialists had to work together. Such an infrastructure also connected Czech research to the wider European OPENSCREEN environment, where access, standardisation, and shared expertise are central principles. The Academy's role in this area shows that internationalisation did not only involve publishing abroad; it involved building national nodes capable of participating in European scientific systems. Czech biology became European partly by becoming infrastructurally compatible with Europe (*CZ-OPENSCREEN, n.d.*; *Research Infrastructures of the Czech Republic, n.d.*).

The Czech Centre for Phenogenomics similarly connected Czech molecular genetics with European and global model-organism research. Mouse and rat models are central to biomedical research, but their use requires high levels of technical standardisation, animal welfare, genetic engineering, phenotyping, imaging, cryopreservation, data management, and preclinical expertise. A centre that combines these capacities becomes more than a service

facility. It becomes a point of entry into international research on gene function, disease models, developmental processes, metabolism, immunity, cancer, neurological disorders, and therapeutic testing. Hosted at the Institute of Molecular Genetics and located at the BIOCEV campus, the Czech Centre for Phenogenomics also embodied the spatial and institutional integration of Academy biology after 1993. It linked an older institute with a newer campus, national infrastructure with European networks, and basic genetics with biomedical relevance. Its participation in INFRAFRONTIER-type environments placed Czech biology within the international system of mouse functional genomics and phenotyping. This changed the scale of what Czech laboratories could do. They could contribute not only isolated experiments, but standardised resources and models usable by wider scientific communities. In the history of the Academy, this marks the transition from institute-based excellence to infrastructure-based international capacity (*INFRAFRONTIER, n.d.*; *Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*).

BIOCEV became one of the most visible spatial symbols of the new networked biology. The centre connected Academy institutes with Charles University and concentrated biotechnology, biomedicine, structural biology, molecular biology, and related fields in a modern research environment near Prague. Its significance was not only architectural or financial. BIOCEV expressed a new institutional philosophy in which Academy institutes and universities could share research infrastructures, doctoral training, technical platforms, and interdisciplinary programmes. This represented a major shift from the older separation between academy research and university education. In molecular and biomedical life sciences, such separation had become increasingly impractical because doctoral students, postdoctoral researchers, advanced equipment, clinical knowledge, and basic biology all needed to interact. BIOCEV also showed how European structural and investment logic affected Czech science. New facilities were expected to increase competitiveness, support regional development, strengthen international recruitment, and improve the translation of research into practice. Yet the most important historical point is that BIOCEV did not replace older institutes. It reorganised their possibilities. The Academy's biological institutes could retain their identities while participating in a shared scientific campus oriented towards European standards of excellence, infrastructure, and collaboration (*Institute of Biotechnology of the Czech Academy of Sciences, n.d.*; *BIOCEV, n.d.*).

The Institute of Biotechnology CAS, established in 2008, belongs to this later generation of Academy biological institutions shaped by European and global scientific networks from the outset. Unlike older institutes that had to adapt from a ČSAV inheritance to a post-socialist environment, the Institute of Biotechnology emerged within a research world already defined by international competition, biomedical molecular biology, technology transfer, and infrastructural cooperation. Its orientation towards basic research in biomedical molecular biology with prospective transfer to human and veterinary medicine shows the changing expectations placed on Academy biology. Research was to remain fundamental, but it was also expected to generate methods, tools, and knowledge capable of moving into broader fields of human activity. This was consistent with European research policy, where excellence and impact increasingly appeared together. The institute's location in BIOCEV reinforced this logic by embedding it in a campus designed for interaction between institutes, university faculties, infrastructure platforms, and potential application. In the institutional history of CAS, the Institute of Biotechnology therefore demonstrates that post-1993 renewal was not only about reforming inherited structures. It also involved creating new biological institutions suited

to the Europeanised knowledge economy. This makes it an important bridge between the Academy's older public-research mission and the newer language of biotechnology, innovation, and translational potential (*Institute of Biotechnology of the Czech Academy of Sciences, n.d.*).

European and global networks also reshaped ecology, evolutionary biology, and biodiversity research. These fields became international not only through grants and publications, but through comparative field systems, global datasets, science-policy platforms, and long-term ecological networks. The Biology Centre CAS, with its institutes in entomology, hydrobiology, parasitology, plant molecular biology, and soil biology, was particularly well positioned for this type of networked science. Its research on freshwater ecosystems, insects, parasites, soils, plants, and biodiversity naturally connected local field knowledge with international questions. A Czech pond, reservoir, forest, meadow, soil system, or insect community could become part of a broader comparative framework. In hydrobiology, the Institute of Hydrobiology was recognised within European ecosystem research networks as a principal Czech institution for complex freshwater research, combining long-term ecological study with methods ranging from chemistry to molecular and isotopic techniques. This shows how field-based biological research became increasingly infrastructural and international in its own way. It did not need only microscopes or sequencing machines; it needed long-term sites, harmonised methods, comparative data, and cross-border ecological interpretation. The Academy's contribution lay in preserving the long-term continuity required for such work while connecting it to European research networks (*Biology Centre CAS, n.d.*; *ALTER-Net, n.d.*).

The globalisation of biodiversity research is especially visible in tropical ecology. Czech entomologists and ecologists associated with the Biology Centre developed long-term research in Papua New Guinea, creating one of the most important examples of Czech biological science operating at a genuinely global scale. This work was not simply a series of expeditions by European scientists to a biodiverse region. It involved long-term field stations, collaboration with local communities, training, ecological monitoring, and sustained research on rainforest insects, plants, food webs, and biodiversity patterns. The significance of this work for the Academy's institutional history is considerable. It shows that a national research institution from Central Europe could become a serious actor in tropical biodiversity science, a field traditionally dominated by larger scientific powers and colonial or postcolonial networks. Czech biology thus moved beyond the narrow idea of reintegration into Europe. It entered global field science through durable partnerships and specialised expertise. Such work also raised questions of ethics, reciprocity, authorship, and the social organisation of biodiversity research. The Academy's global role depended not only on scientific excellence, but on the capacity to build responsible and respectful international collaborations. Tropical ecology therefore expanded both the scientific and moral geography of Czech Academy biology (*Academy of Sciences of the Czech Republic, 2022*; *Novotný & Toko, 2015*).

Biodiversity networks also increasingly involved global consortia based on harmonised data collection. The DarkDivNet project, in which Czech researchers from the Institute of Botany and other institutions contributed data and methodology, is a clear example. By studying "dark diversity", or the native species that could potentially occur in a community but are absent, the project moved beyond simple species counts. It required sampling across thousands of sites and many regions, using comparable methods that could reveal hidden effects of human disturbance. The participation of Czech botanists in such work demonstrates the international value of long-established local expertise. Czech vegetation science, with its strong taxonomic

and phytosociological traditions, could contribute to a global network precisely because it had preserved detailed knowledge of plants, communities, and landscapes. At the same time, global projects changed the meaning of local data. A plot in the Krkonoše Mountains, Šumava, Podyjí, Ralsko, or the Novohradské Mountains became part of a worldwide analysis of vegetation impoverishment. This is one of the defining features of contemporary biodiversity science: local observation becomes globally meaningful when placed in a standardised comparative network. The Academy's botanical tradition therefore entered global ecology not by abandoning field specificity, but by making it comparable (*Pärtel et al., 2025*; *Masaryk University, 2025*).

Science-policy networks became another important arena for Academy biology. Ecology and biodiversity research increasingly had to inform public decision-making at national, European, and global levels. The representation of the Institute of Botany in the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services illustrates this development. IPBES is not a conventional academic society. It is a science-policy body that assesses biodiversity and ecosystem services for governments and international organisations. Participation in such a platform requires a different form of scientific communication. Researchers must present evidence, uncertainty, scenarios, and policy implications without surrendering scientific independence. For the Academy, this role was historically significant because it extended the old function of expert advice into the global environmental governance system. Czech ecological knowledge became part of international assessments that could influence conservation priorities and policy frameworks. This also changed the public responsibility of ecological research. It was no longer enough to publish excellent papers on plant communities, invasions, or biodiversity loss. Scientists increasingly had to help society interpret what such findings meant for land use, protected areas, restoration, agriculture, forestry, and climate adaptation (*Institute of Botany of the Czech Academy of Sciences, 2026*; *IPBES, n.d.*).

Strategy AV21 added a specifically Academy-wide dimension to this science-policy orientation. Its declared emphasis on top research in the public interest placed biological research within a broader institutional strategy that connected CAS institutes, universities, industry, state bodies, and public-sector partners. The 2026 launch of the programme "Global Biodiversity Crisis: Risks and Opportunities for Human Society" showed that biodiversity had become one of the strategic themes through which the Academy addressed contemporary societal challenges. This was important because it moved biodiversity from the margins of natural history to the centre of public research policy. The programme's framing recognised that habitat destruction, intensive agriculture, and the decline of wild plants and animals are not merely scientific concerns but risks for human society. Such a framing did not turn the Academy into a political advocacy organisation. Rather, it acknowledged that high-quality science can and should inform public action when society faces long-term risks. Strategy AV21 thus provided an institutional bridge between fundamental biological research and science for policymaking. It also helped integrate institutes that might otherwise remain separated by discipline, geography, or method. In the context of post-1993 history, this shows how the Academy's autonomy gradually became linked with its capacity to organise knowledge around public problems (*Academy of Sciences of the Czech Republic, 2026*; *Strategy AV21, n.d.*).

International networks also transformed doctoral training and early-career development. Biology after 1993 increasingly depended on young scientists who could move across countries, learn advanced methods abroad, return with new expertise, or maintain

international collaborations from Czech laboratories. Doctoral students and postdoctoral researchers became carriers of internationalisation. They brought new techniques, publication habits, ethical norms, data practices, and expectations of laboratory culture. European mobility schemes, Marie Skłodowska-Curie networks, Erasmus-related cooperation, and bilateral projects all contributed to this circulation. Academy institutes, although not universities in the formal sense, became central training environments through their cooperation with universities and their participation in international projects. BIOCEV's postgraduate environment, the Biology Centre's links with the University of South Bohemia, and the research groups of the Institute of Molecular Genetics, Institute of Botany, Institute of Microbiology, Institute of Experimental Botany, and other institutes all participated in this transformation. The consequence was a gradual change in scientific identity. A Czech biologist trained after 1993 increasingly belonged not only to a national academic tradition but also to an international cohort shaped by shared conferences, methods, software, journals, and grant cultures. This generational dimension was crucial because networks survive only when they are reproduced through people, not only through institutions (*BIOCEV, n.d.*; *Czech Academy of Sciences, n.d.*).

International advisory boards and external evaluation formed another layer of biological internationalisation. After 1993, the Academy had to develop mechanisms for assessing institutes according to standards that were not merely national or administrative. International peer review became one of the tools through which institutional quality could be measured and improved. For biology, this mattered because the pace of methodological change was rapid and local judgement alone could easily become self-protective. External evaluators could compare Czech laboratories with European and global standards in publication output, infrastructure use, doctoral training, recruitment, project success, and strategic direction. Such evaluation was not always comfortable. It exposed weaknesses, encouraged restructuring, and sometimes placed pressure on inherited research groups. Yet it also protected institutes from provincialism and helped justify public investment in expensive fields. Evaluation thus became a form of international communication. The Academy showed the state and the scientific community that its biological institutes could be assessed by peers from abroad. This reinforced autonomy because it grounded institutional legitimacy in scientific quality rather than political patronage. The post-1993 Academy therefore learned to defend itself not by claiming historical prestige alone, but by subjecting that prestige to international judgement (*Czech Academy of Sciences, n.d.*).

Publication practices changed in parallel with these institutional mechanisms. International co-authorship, English-language journals, open-access publishing, citation networks, and journal-based evaluation all became part of everyday biological science. This shift was not merely linguistic. It altered the scale at which research questions were formulated. A study of a Czech plant community, freshwater reservoir, parasite, microbial process, gene, or cellular pathway had to be framed in ways that could matter to an international readership. This encouraged abstraction, comparison, and theoretical ambition. It also created pressure to produce results quickly and visibly, sometimes at the expense of slower descriptive or long-term work. The Academy's biological institutes had to manage this tension carefully. Taxonomy, long-term monitoring, and regional ecological expertise remained essential, even when they were less easily rewarded by high-impact publication metrics. Molecular biology, by contrast, could often fit more readily into global journal cultures, but it too risked metric-driven fragmentation. International publication thus brought both liberation and discipline. It allowed

Czech biology to be seen, but it also subjected it to global competition and changing editorial fashions. The history of Academy biology after 1993 must therefore recognise publication not only as output, but as a networked social system shaping what scientists considered publishable, important, and fundable (*Leydesdorff et al., 2013*; *Czech Academy of Sciences, n.d.*).

Open science and FAIR data principles added a further dimension to this transformation. In the life sciences, openness concerns not only articles but also datasets, code, metadata, protocols, images, biological resources, and research materials. European policy increasingly encouraged researchers to make data accessible, interoperable, and reusable, while respecting ethical and legal constraints. For Czech Academy biology, this created both opportunities and responsibilities. Open data could make Czech datasets more visible and valuable, especially in biodiversity, genomics, imaging, phenotyping, and environmental monitoring. At the same time, it required infrastructure, training, curation, and careful governance. Not all biological data can be opened without restriction: human-related biomedical data, sensitive species locations, animal research, and preclinical information require protective rules. The phrase “as open as possible, as closed as necessary” captures this balancing act. Academy institutes had to become data-governing institutions as well as knowledge-producing institutions. This was a major change from earlier research cultures in which data often remained inside notebooks, collections, or local files. The Europeanisation of Czech biology therefore involved a new ethics of data stewardship (*Antol et al., 2024*; *European Research Council, 2022*).

International networks also intensified the relationship between biology and innovation. Biotechnology, biomedical molecular biology, chemical screening, plant biotechnology, microbial applications, diagnostics, and preclinical research all connected Academy institutes with potential users beyond the academic world. European projects often required attention to impact, dissemination, exploitation, and stakeholder engagement. This did not mean that the Academy abandoned basic science. Rather, it learned to articulate basic research within broader innovation ecosystems. The Institute of Biotechnology, CZ-OPENSCREEN, BIOCEV, the Czech Centre for Phenogenomics, and technology-transfer structures exemplify this shift. Biological knowledge could move towards diagnostics, therapeutics, veterinary medicine, agriculture, environmental applications, or industrial processes. Yet the strongest innovation potential usually rested on long-term fundamental competence. A probe, model organism, diagnostic method, plant variety, microbial product, or imaging technique cannot emerge from policy rhetoric alone. It requires laboratories, trained people, infrastructures, and freedom to pursue mechanisms whose application may not be immediately obvious. International networks helped by connecting Czech institutes with partners, standards, and markets, but they did not replace the Academy’s central task: sustained public research. Innovation became one possible trajectory of biological knowledge, not its only justification (*Institute of Biotechnology of the Czech Academy of Sciences, n.d.*; *CZ-OPENSCREEN, n.d.*).

Health crises revealed the practical importance of such networked biology. The COVID-19 pandemic made molecular diagnostics, sequencing, epidemiological expertise, data sharing, and biomedical infrastructures visible to the public. Although pandemic response involved universities, hospitals, public-health authorities, and private laboratories as well as Academy institutes, it showed why a country needs strong biological research capacity before a crisis arrives. Laboratories that had been built for fundamental molecular, microbial, biomedical, or genomic work could be mobilised for testing, surveillance, method development, and expert

advice. The crisis also showed that national capacity and international networking are inseparable. Viruses move globally, variants are tracked through international data systems, and public-health interpretation depends on comparative evidence. Czech biological research therefore became part of a wider global knowledge infrastructure responding to uncertainty. This was historically important because it reinforced the public legitimacy of the Academy's life sciences. Decades of investment in molecular and biomedical competence were suddenly seen not as abstract academic spending, but as part of societal resilience. The pandemic thus revealed a broader truth about post-1993 Academy biology: international networks are not external ornaments of science, but conditions of preparedness in a connected world (*Šúri et al., 2025*).

The same logic applies to environmental crisis. Biodiversity loss, invasive species, climate change, freshwater degradation, soil transformation, and ecosystem collapse cannot be understood within national borders alone. Czech ecological data matter because they are part of continental and global patterns. European biodiversity strategies, IPBES assessments, global plant-diversity studies, invasion-science networks, and comparative ecosystem research all require national expertise organised internationally. The Institute of Botany, Biology Centre, Institute of Vertebrate Biology, Institute of Animal Physiology and Genetics, and related Academy groups contributed to this system through field observations, databases, taxonomic knowledge, ecological theory, and policy-relevant interpretation. Here again, networks did not erase locality. A Czech meadow, forest, river, pond, or soil community has its own history, but it also participates in larger processes: climate warming, nitrogen deposition, land-use change, fragmentation, alien species movement, and regional species decline. The Academy's ecological institutes were valuable because they could connect these scales. They preserved knowledge of the Czech landscape while making it meaningful for Europe and the world. This ability to move between local specificity and global interpretation became one of the defining strengths of post-1993 biological research (*Pärtel et al., 2025*; *Institute of Botany of the Czech Academy of Sciences, 2026*).

The globalisation of science also brought new inequalities and ethical questions. Czech biology after 1993 was itself shaped by the experience of entering networks historically dominated by older Western European and North American institutions. This gave Czech researchers a particular position: they were no longer isolated, but they still worked within asymmetrical structures of funding, prestige, salaries, and access. In global biodiversity research, similar asymmetries are even more visible. Research in tropical regions, biodiversity-rich countries, or economically less powerful scientific systems raises questions about local participation, authorship, benefit sharing, and scientific sovereignty. Czech Academy researchers involved in global fieldwork had to navigate these issues carefully. Responsible internationalisation requires more than extracting data from distant places and publishing them in European journals. It requires long-term partnerships, local training, respect for communities, and recognition of knowledge produced outside traditional centres of power. This ethical dimension became increasingly important in 21st-century biodiversity science. For the Academy, global networks therefore meant not only opportunity and prestige, but also responsibility. Czech biology's international maturity can be measured partly by its capacity to participate in global science without reproducing the most problematic habits of unequal knowledge extraction (*Novotný & Toko, 2015*; *Biology Centre CAS, 2025*).

The relationship between national scientific identity and international integration was not simple. Some observers might assume that the more Czech biology became European and

global, the less distinctly Czech it became. The institutional history of the Academy suggests the opposite. Internationalisation strengthened the value of national traditions when those traditions could contribute something distinctive. Czech vegetation science, entomology, hydrobiology, parasitology, immunology, molecular genetics, plant biology, microbiology, and experimental medicine became internationally visible because they had accumulated specific forms of expertise. The Academy's role was to provide continuity, infrastructure, and public legitimacy for this expertise while allowing it to enter broader networks. National identity therefore did not mean isolation or self-celebration. It meant the capacity to contribute from a historically formed position. In this sense, Czech biological research after 1993 became both less provincial and more self-aware. It no longer needed to prove itself by imitation alone. It could participate in global science through fields where Czech expertise had depth, data, collections, field experience, or technical strength. The Academy's institutional memory became more valuable when it was opened to international exchange (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Institute of Botany of the Czech Academy of Sciences, n.d.*).

The cultural change inside biological institutes was equally important. International networks altered seminar culture, laboratory management, recruitment, authorship practices, mentoring, and expectations of scientific communication. Foreign postdoctoral researchers and doctoral students became more common in strong institutes and centres. Czech scientists returning from abroad often brought with them different habits of group leadership, peer discussion, grant planning, and publication strategy. International advisory boards and reviewers encouraged institutes to compare themselves with research environments in Germany, Austria, France, the United Kingdom, the Netherlands, Scandinavia, Switzerland, and the United States. This comparison could be demanding, but it also helped loosen older hierarchical habits inherited from socialist-era science. Younger researchers could gain authority through publications, grants, and international recognition rather than only through seniority. At the same time, internationalisation created pressures: precarious careers, grant dependence, publication stress, and competition for talent. The Academy's biological institutes had to reconcile openness with stability. They needed to be attractive to international researchers while remaining responsible to Czech public science and domestic training. This balancing act became a central feature of post-1993 institutional life (*Czech Academy of Sciences, n.d.*).

The Academy's biological networks also depended on cooperation with Czech universities. European and global integration strengthened, rather than weakened, the need for domestic partnerships. Charles University, Masaryk University, the University of South Bohemia, Palacký University, Czech University of Life Sciences, and other institutions formed overlapping networks with Academy institutes. This was visible in BIOCEV, Czech-BioImaging, doctoral programmes, biodiversity projects, plant research, biomedical science, and regional ecological studies. The older institutional distinction between academy research and university teaching did not disappear, but it became more permeable. This mattered for internationalisation because European projects often require training capacity, interdisciplinary teams, and institutional critical mass. Academy institutes alone could not carry the full burden of education, while universities alone often lacked specialised long-term infrastructures. Together, they could create stronger research environments. This domestic networking was a precondition for international networking. Czech biology entered European and global science more effectively when national institutions cooperated rather than

competed defensively. The post-1993 Academy thus helped reshape the Czech research system as a networked ecology of institutes, universities, infrastructures, and public agencies (*BIOCEV, n.d.*; *Czech-BioImaging, n.d.*).

International biological networks also affected the Academy's relationship with the state. Under socialism, international cooperation could be politically controlled and symbolically used by the regime. After 1993, the state's role changed but did not disappear. The Czech state remained a major funder and policy actor, while European participation required national coordination, co-financing, legal adaptation, and diplomatic representation in research policy. CAS therefore had to communicate with ministries, the Technology Centre Prague, European offices, and international policy structures. The Academy's European Research Area activities show that internationalisation became part of institutional strategy, not merely the sum of individual collaborations. Biology benefited from this because life-science infrastructures often require state-level decisions and long-term investment. A sequencing or imaging platform, phenogenomics centre, or biodiversity monitoring network cannot be sustained by a single grant alone. The state had to recognise that participation in European science required stable domestic institutions. At the same time, the Academy had to show that public investment produced scientific value, international visibility, and societal benefit. This changed the old autonomy-state relationship. Scientific autonomy survived not by withdrawing from policy, but by proving its value within a democratic and Europeanised research system (*Czech Academy of Sciences, n.d.*; *Horizon Europe Portal, 2026*).

By the 2020s, Czech Academy biology had become a multi-layered networked system. At one layer stood the institutes themselves, with their histories, research groups, infrastructures, and disciplinary cultures. At another layer stood national platforms linking Academy institutes with universities, hospitals, public agencies, and technology-transfer bodies. At a third layer stood European infrastructures, Framework Programme projects, ERC grants, mobility schemes, and policy agendas. At a 4th layer stood global research communities concerned with biodiversity, tropical ecology, infectious diseases, genomics, data, climate change, and biological resources. The important historical point is that these layers did not replace one another. They interacted. A plant ecologist might work in a Czech landscape, use a national database, publish within a global consortium, and contribute to European conservation policy. A molecular biologist might work in an Academy laboratory, use a Czech infrastructure node, collaborate with a European project, and deposit data in international repositories. A parasitologist might study local host systems while participating in global debates on disease ecology and evolution. This layered structure became the normal condition of biological research after 1993. The Academy's achievement was to make such layering institutionally sustainable (*ELIXIR CZ, n.d.*; *Biology Centre CAS, n.d.*; *Institute of Botany of the Czech Academy of Sciences, 2026*).

This networked development also changed the historical meaning of "Czech biology". In the 19th century and the period of national revival, scientific work was often tied to building cultural and national self-knowledge. In the Czechoslovak Academy, science became part of a state-socialist project of planned modernity, even when individual scientists pursued more universal aims. After 1993, Czech biology became a national science operating through transnational forms. Its Czech character lay in institutions, personnel, field sites, public funding, language of domestic communication, and responsibility to Czech society. Its scientific character, however, increasingly depended on international standards, English-language publication, European infrastructures, and global comparison. This duality was not a weakness. It reflected

the normal condition of science in a small European country. The Academy's biological institutes could not and did not aim for self-sufficiency. Their task was to become strong nodes in wider networks while preserving the continuity necessary for serious research. In this sense, biological research after 1993 offers a condensed picture of the Academy's modern identity: nationally rooted, institutionally autonomous, internationally evaluated, infrastructurally connected, and publicly responsible (*European Commission, 2026*; *Czech Academy of Sciences, n.d.*).

Thus, biological research in European and global networks after 1993 became one of the most important expressions of the Czech Academy's post-socialist transformation. Internationalisation was not limited to more travel, more English-language articles, or more foreign partners. It reshaped the institutional architecture of Czech biology through European Research Area policies, Framework Programmes, ERC competition, research infrastructures, open data, doctoral mobility, science-policy platforms, biodiversity consortia, global fieldwork, and cooperation between Academy institutes and universities. Molecular biology, genetics, cell biology, ecology, evolutionary biology, parasitology, microbiology, plant science, and biomedical research all entered networked environments, but they did so in different ways: through genomics and imaging, through phenogenomics and chemical biology, through freshwater and tropical field systems, through global biodiversity datasets, and through policy bodies such as IPBES. The result was a new form of institutional autonomy. The Academy remained a Czech public research institution, but its biological sciences became credible and productive because they were internationally embedded. This history shows that continuity and renewal were joined by a third principle: connectivity. Without networks, the Academy's biological institutes would have preserved expertise but risked provincialism. Through networks, they transformed inherited Czechoslovak strengths into contemporary European and global scientific capacity.

Biomedicine and Public Health Relevance

1. Biomedical Institutes and Translational Potential

After 1993, biomedical research within the Academy of Sciences of the Czech Republic developed at the intersection of continuity, reform, and changing social expectation. The Academy did not become a clinical hospital system, nor did it try to replace universities, medical faculties, or specialised medical centres. Its distinctive role was different: it provided a public institutional space for basic biomedical research, where mechanisms of disease, cellular processes, physiological regulation, molecular pathology, biomaterials, microbiology, pharmacology, genetics, toxicology, neuroscience, and biotechnology could be studied before they became clinical routines. This distinction is central to understanding the Academy's post-socialist biomedical profile. Translational potential did not mean a simple administrative command to "apply" science as quickly as possible. It meant that fundamental research was increasingly organised in such a way that its results could, under appropriate conditions, move towards diagnostics, therapeutic strategies, regenerative medicine, pharmacological

development, medical materials, disease models, or clinical cooperation. The post-1993 period therefore required a new vocabulary for the life sciences. Older terms such as physiology, pathology, microbiology, biochemistry, and experimental medicine remained important, but they were increasingly joined by molecular medicine, biomedical molecular biology, translational medicine, preclinical models, biomarkers, tissue engineering, phenogenomics, bioimaging, and technology transfer. This vocabulary reflected more than scientific fashion. It marked a transformation in the social contract between the Academy, the state, and society. Biomedical institutes were expected to produce knowledge of high international quality, but also to show why such knowledge mattered for health, ageing, disease prevention, diagnosis, and future treatment. The Academy's biomedical sector thus became one of the places where scientific autonomy and public usefulness had to be held together without reducing one to the other (*Czech Academy of Sciences, 2026*; *Institute of Experimental Medicine of the CAS, n.d.*).

The formation of the Czech Academy after the dissolution of the Czechoslovak Academy of Sciences gave biomedical research a new institutional framework. Under ČSAV, many biomedical and life-science institutes had been embedded in a state-socialist system that valued scientific modernisation but also shaped research through political priorities, central planning, and limited international exchange. After 1993, these institutes entered a more plural and competitive research environment. Their legitimacy could no longer rely on inherited prestige alone. It had to be demonstrated through peer-reviewed publications, international cooperation, grant success, infrastructure development, doctoral training, and relevance to national and European research strategies. Biomedical research was particularly affected because medicine itself was changing rapidly. Molecular biology, imaging, genomics, pharmacology, cell therapy, biomaterials, and computational analysis were transforming the boundaries between laboratory and clinic. The Academy's institutes had to adapt to this environment while preserving the long-term exploratory work that hospitals and short-term applied projects often cannot sustain. This produced a distinctive institutional arrangement. The Academy's biomedical institutes worked upstream from clinical practice, but not outside the biomedical world. They studied mechanisms, models, and technologies that might later enter prevention, diagnostics, or therapy through collaboration with universities, hospitals, companies, and European infrastructures. In this sense, the post-1993 biomedical Academy was neither purely theoretical nor narrowly applied. It was a mechanism-producing system, and its translational potential depended precisely on the depth of its basic research (*Czech Academy of Sciences, n.d.*; *EATRIS, n.d.*).

The Section of Biological and Medical Sciences became the main organisational home for this profile. Its institutes included the Institute of Biophysics, the Institute of Biotechnology, the Institute of Physiology, the Institute of Microbiology, the Institute of Experimental Botany, the Institute of Experimental Medicine, the Institute of Molecular Genetics, and the Institute of Animal Physiology and Genetics. This list is historically revealing because it does not map neatly onto the structure of clinical medicine. Instead, it represents a broad experimental biology of health and disease. Biophysics links physical methods with DNA, chromatin, radiation, molecular mechanisms, and cancer-related questions. Biotechnology works at the level of biomedical molecular biology and technological transfer. Physiology studies normal and pathological functions, especially where mechanisms of disease can be clarified. Microbiology connects microbial life, immunity, infection, biotechnology, and host-environment relations. Experimental medicine provides a wide biomedical spectrum, from

neurobiology and stem cells to cancer, toxicology, pathology, and regenerative approaches. Molecular genetics contributes to gene regulation, genome integrity, immunology, developmental mechanisms, and disease models. Animal physiology and genetics connects organismal models, reproduction, genome function, and comparative biology. The result is not a medical faculty under another name, but a distributed system of experimental biomedical knowledge inside a national academy. Its strength lies in its capacity to move between molecule, cell, tissue, organism, model, material, and potential application (*Czech Academy of Sciences, 2026*).

The Institute of Experimental Medicine occupies a particularly important position in this biomedical constellation. Founded in 1975 and later transformed under the public research institution framework, it became one of the Academy's principal centres for complex biomedical research. Its present profile includes diagnostic markers, treatment of serious diseases associated with ageing, neurodegeneration, trauma, ischaemia, musculoskeletal disorders, cancer, degenerative changes in vision and hearing, and the impact of environmental pollution on human health. This range is significant because it shows how experimental medicine after 1993 moved beyond any single disease category. It became a platform for studying the biological vulnerability of the human body under conditions of ageing, injury, toxic exposure, and chronic degeneration. The institute's biomedical orientation therefore corresponded closely to the demographic and social challenges of late 20th- and early 21st-century Europe. Ageing societies require knowledge about neurodegeneration, tissue damage, sensory decline, cancer, and chronic disease. They also require understanding of environmental determinants of health, because disease cannot be fully explained by genes and cells alone. The Institute of Experimental Medicine's translational potential lay in this broad mechanistic engagement with medical problems. It did not provide routine treatment, but it produced the kinds of experimental knowledge without which new treatments and diagnostic approaches would remain shallow or speculative (*Institute of Experimental Medicine of the CAS, n.d.*; *Institute of Experimental Medicine of the CAS, n.d.*).

The institutional history of the Institute of Experimental Medicine also illustrates the change in biomedical governance after 1993. The institute became a public research institution under the Act on Public Research Institutions, and its internal organisation developed around research departments rather than a single monolithic programme. This organisational form mattered because biomedical research had become too complex to be directed by one disciplinary language. Neurobiology, molecular embryology, cancer research, genetic toxicology, nanotoxicology, tissue replacement, stem cells, pathology, developmental biology, and environmental health require different methods and professional cultures. Their coexistence inside one institute created opportunities for interaction but also required managerial flexibility. Translational potential often emerges at exactly these boundaries. A stem-cell project may need imaging, biomaterials, animal models, molecular markers, and clinical consultation. A neurodegeneration project may depend on cellular pathology, molecular signalling, toxicology, and electrophysiology. A cancer project may require genomics, cell biology, pharmacology, and tissue analysis. The institute therefore became a microcosm of modern biomedical research: multidisciplinary, infrastructural, ethically regulated, and increasingly connected to national and European networks. Its importance in the Academy's institutional history lies not only in particular research results, but in its demonstration that public non-university institutes could host sophisticated biomedical

environments with long-term continuity (*Institute of Experimental Medicine of the CAS, n.d.*; *EATRIS-CZ, n.d.*).

The Institute of Physiology represented another major pillar of Academy biomedicine. Its mission after 1993 can be understood through the study of normal and pathological physiological mechanisms. This phrase may sound traditional, but it became highly modern in the post-socialist period. Physiology was no longer limited to organ-level description or classical functional measurements. It increasingly included molecular, cellular, systemic, and integrative approaches to disease mechanisms. The Institute of Physiology described its work in relation to improving prevention, diagnosis, and treatment of serious non-infectious diseases. This positioned the institute within one of the central biomedical problems of contemporary Europe. Non-infectious diseases, including cardiovascular, metabolic, neurological, and other chronic disorders, became major burdens for health systems and ageing societies. The Academy's contribution was not to manage hospitals, but to clarify mechanisms: how cells, tissues, organs, and regulatory systems operate under normal and pathological conditions. Such knowledge is a precondition for rational diagnostics and therapy. The Institute of Physiology thus preserved an older Academy tradition of experimental physiology while adapting it to molecular medicine, imaging, bioenergetics, neurophysiology, cardiovascular research, metabolism, and translational cooperation (*Institute of Physiology of the Czech Academy of Sciences, n.d.*; *Kopecký, 2015*).

Physiology also had special institutional value because it bridged scales more explicitly than many other disciplines. Molecular biology may sometimes focus intensely on genes or pathways, while clinical medicine may focus on the patient and disease category. Physiology asks how functions are organised across cells, tissues, organs, and whole organisms. This makes it particularly important for translational research, because many promising molecular findings fail when they are not understood at the level of organismal function. The Institute of Physiology's research on normal and pathological mechanisms therefore occupied a strategic middle ground. It could connect molecular findings with systemic consequences. It could use experimental models to clarify disease processes before clinical application. It could provide expertise relevant to prevention and diagnosis without being absorbed into routine clinical service. After 1993, this bridging role became more important as biomedicine moved towards systems thinking, personalised medicine, and complex disease models. The Academy's physiological research thus contributed to a broader rebalancing of biomedical science: from isolated molecular targets to integrated mechanisms of health and disease. Its translational potential was not a late addition to physiology, but an intrinsic consequence of studying living functions in their organised complexity (*Institute of Physiology of the Czech Academy of Sciences, n.d.*).

The Institute of Biotechnology, established in 2008, marked a different phase of Academy biomedical development. Unlike older institutes that carried strong ČSAV inheritances into the post-1993 period, the Institute of Biotechnology was born in an already Europeanised and infrastructure-oriented research landscape. Its declared focus on excellent basic research in biomedical molecular biology with prospective transfer of biotechnological methods and tools to human and veterinary medicine expressed the new language of 21st-century life science. The institute was not created merely to preserve an inherited discipline. It was designed to operate in a zone where molecular biology, biotechnology, structural biology, medicine, and innovation policy overlapped. Its location within the BIOCEV environment further reinforced this role. Biotechnology after 1993 was not simply industrial biology. It involved protein

engineering, structural studies, molecular mechanisms, disease models, cell-based systems, and the development of tools that could later support diagnosis or therapy. The Institute of Biotechnology thus represented the Academy's ability to create new institutional forms when older structures were insufficient for emerging scientific fields. Its significance lies in the fact that it placed translational potential into the institute's founding identity, while still grounding that potential in basic research. This is an important distinction because the Academy's strongest biomedical contribution has usually come from research that was fundamental in method but open to future application in purpose (*Institute of Biotechnology of the Czech Academy of Sciences, n.d.*).

BIOCEV, the Biotechnology and Biomedicine Centre of the Academy of Sciences and Charles University, became one of the most visible symbols of this new stage. The centre brought together Academy institutes and Charles University faculties in a shared environment oriented towards biotechnology, biomedicine, structural biology, and advanced facilities. Its completion and transition to full operation in 2015–2016 marked the institutional consolidation of a long post-1993 process: the movement from separated research islands towards interdisciplinary campuses. BIOCEV mattered not only because it provided laboratories and infrastructure, but because it altered the relationship between the Academy and the university sector. Biomedical research requires doctoral students, medical knowledge, molecular expertise, technical platforms, animal models, imaging, proteomics, genomics, structural biology, and potential links to clinical questions. No single institution can easily provide all these elements alone. BIOCEV therefore created a shared space where the Academy's long-term research culture could interact with Charles University's educational and medical capacities. It was a practical answer to a structural problem inherited from the socialist period, when academy research and university education had often been institutionally separated. In the biomedical field, this separation became increasingly counterproductive after 1993. BIOCEV helped overcome it by offering a model of integrated research, training, and translational infrastructure (*BIOCEV, n.d.*; *Institute of Molecular Genetics of the Czech Academy of Sciences, 2015*).

The Institute of Molecular Genetics remained central to translational potential, even when its identity was not primarily clinical. Its history from Czechoslovak immunogenetics, retrovirology, and molecular biology gave it a strong foundation for modern biomedical research. After 1993, its work in genome regulation, cell biology, immunology, cancer biology, developmental mechanisms, virology, and phenogenomics made it one of the Academy's most important biomedical nodes. Its significance lay in the fact that many translational trajectories begin with molecular understanding. Cancer diagnostics, immune therapies, gene function analysis, disease modelling, and pharmacological exploration all require knowledge of how genes, cells, and regulatory networks operate. The Institute of Molecular Genetics also hosted or participated in major infrastructures such as the Czech Centre for Phenogenomics, Czech-BioImaging, ELIXIR CZ, and CZ-OPENSCREEN. These infrastructures turned molecular biology into a shared national capacity. They also made translational work more realistic because diagnostic and therapeutic development requires standardised models, imaging, data, screening, and reproducible experimental systems. The institute therefore illustrates a crucial point: translational potential is not located only in institutes labelled "medical". It often lies in basic biological institutes whose mechanisms, tools, and models later become indispensable for medicine (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*).

The Czech Centre for Phenogenomics deserves particular attention in this context. Modern biomedicine depends heavily on model organisms, especially genetically modified mice and rats, to understand gene function, disease mechanisms, and therapeutic effects. Yet model-organism research is no longer a matter of small animal rooms attached to individual laboratories. It requires genetic engineering, phenotyping pipelines, imaging, pathology, metabolism, behavioural tests, data analysis, cryopreservation, animal welfare regulation, and international standardisation. The Czech Centre for Phenogenomics, located at BIOCEV and linked with the Institute of Molecular Genetics, provided precisely this type of infrastructural capacity. Its translational importance is clear. Before a therapy can move towards human use, researchers need robust preclinical models. Before a gene can be interpreted medically, researchers need evidence of its functional role in living organisms. Phenogenomics therefore bridges molecular genetics and medical interpretation. It also links national research capacity to European model-organism networks. In the Academy's institutional history, such a centre marks the passage from traditional institute laboratories to infrastructural platforms capable of serving many users and many disease-related questions (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *INFRAFRONTIER, n.d.*).

The Institute of Microbiology also contributed to biomedical and translational potential, although its research identity extended beyond medicine into ecology, biotechnology, and microbial systems. Microbiology is inherently translational because microorganisms are at once experimental models, sources of bioactive compounds, agents of disease, components of the microbiome, tools of biotechnology, and participants in environmental processes. After 1993, the Institute of Microbiology's work connected microbial physiology, molecular microbiology, immunology, biotechnology, biosynthesis of natural products, environmental microbiology, and host-microbe relations. This breadth made it valuable in several translational directions. It could contribute to understanding infection, immunity, microbial metabolites, natural products, antibiotics, biotechnology, and microbial interactions relevant to health. It also occupied a strategic position during periods when infectious disease and antimicrobial resistance became global concerns. The institute's biomedical relevance therefore did not depend solely on direct clinical projects. It lay in sustaining fundamental knowledge of microorganisms and their interactions with hosts and environments. In a period when microbiome research, immunology, pathogen surveillance, and biotechnology were all becoming more important, the Academy's microbiological capacity became part of the Czech Republic's long-term biomedical resilience (*Institute of Microbiology of the Czech Academy of Sciences, n.d.*; *EATRIS-CZ, n.d.*).

The Institute of Biophysics in Brno added another important dimension to Academy biomedicine. Biophysics brings physical concepts and methods into the study of biological systems, and in the biomedical context it is especially relevant to DNA damage, chromatin organisation, radiation biology, molecular pharmacology, cellular responses, cancer mechanisms, and imaging. Its location in Brno also strengthened the decentralised geography of biomedical research within the Academy. Prague was important, but Academy biomedicine was not exclusively Prague-based. Brno, with its universities, hospitals, and scientific institutes, provided another environment for biomedical interaction. The biophysical approach mattered because many disease processes are not only chemical or genetic; they are spatial, mechanical, energetic, structural, and dynamic. DNA repair, chromatin architecture, protein interactions, radiation response, and cellular organisation all require methods drawn from physics, chemistry, biology, and computational analysis. The Institute of Biophysics therefore

exemplified the Academy's interdisciplinary character. Its translational potential was not immediate in the sense of producing a clinical service, but it was deep in the sense of clarifying mechanisms relevant to cancer, genome stability, and pharmacological action. Such work belongs to the preclinical foundation on which more visible medical applications later depend (*Institute of Biophysics of the Czech Academy of Sciences, n.d.*).

The Institute of Organic Chemistry and Biochemistry represents perhaps the most famous Czech example of the long path from basic research to medical application. Although it belongs formally to the chemical sciences rather than the biological and medical section, its relevance to biomedical translational potential is impossible to ignore. The work of Antonín Holý on modified nucleosides and nucleotides, and the subsequent development of antiviral drugs in cooperation with Gilead Sciences, became one of the most striking success stories in the history of Czech research. Its historical significance is twofold. First, it shows that major medical applications may arise from basic chemical and biochemical research pursued over many years. Second, it demonstrates that successful translation requires international industrial partnership, patent strategy, licensing, and institutional support. After 1993, IOCB's experience influenced the Academy's understanding of technology transfer. It showed that public research could generate discoveries of global medical importance without abandoning academic science. The institute's collaboration with Gilead, including the Gilead Sciences Research Centre at IOCB Prague, became a model of how Czech Academy research could enter the international biomedical innovation system. This example also gave the Academy a powerful argument in public debates about the value of basic research: one cannot always predict which fundamental investigations will later become medically transformative (*Institute of Organic Chemistry and Biochemistry of the CAS, n.d.*; *Institute of Organic Chemistry and Biochemistry of the CAS, n.d.*).

The establishment of i&i Prague by IOCB in 2017 further institutionalised this lesson. Technology transfer had long been one of the weaker elements in many post-socialist research systems. Scientists could produce valuable results, but they often lacked the legal, financial, managerial, and commercial support needed to protect inventions, find partners, develop companies, or negotiate licensing. i&i Prague was created to support the commercialisation of Czech research results and to help academic institutions identify and protect inventions with commercial potential. Its significance extended beyond IOCB itself. It suggested that technology transfer could become a professionalised service for the wider Czech research environment. In the biomedical field, this mattered because translation is especially complex. A potential therapy, diagnostic method, compound, biomaterial, or device must move through intellectual-property protection, validation, regulation, investment, industrial development, and often clinical trials. Individual scientists cannot manage this process alone. The creation of dedicated transfer structures therefore marked an institutional maturation of the Academy's translational potential. It also reflected a broader post-1993 shift: public research institutions were increasingly expected to take responsibility not only for discovery, but also for pathways by which discovery might benefit society (*Institute of Organic Chemistry and Biochemistry of the CAS, 2017*).

The opening of an IOCB presence in Boston in 2024 added a further international dimension to this story. Boston is one of the world's major centres of biotechnology, medicinal chemistry, venture capital, and biomedical entrepreneurship. By establishing an outpost there through its technology-transfer structures, IOCB signalled that Czech Academy science could seek direct engagement with one of the central global ecosystems of biomedical innovation. This was

historically significant because it showed how far the Academy had moved from the late socialist condition of restricted international circulation. A Czech institute was no longer only trying to enter European networks; it was placing itself in a global biomedical marketplace of ideas, partnerships, investors, and start-up trajectories. Such a move also reveals the changing scale of translational ambition. Medical application is rarely national in scope. A compound, platform, diagnostic tool, or therapeutic strategy must often connect with global industry, regulation, capital, and expertise. The Boston initiative therefore represented a new kind of institutional diplomacy for Czech science. It extended the Academy's biomedical horizon beyond publication and cooperation towards active positioning within international innovation systems (*Academy of Sciences of the Czech Republic, 2024*).

The Institute of Macromolecular Chemistry contributed to biomedical potential through polymers, hydrogels, biomaterials, and tissue-engineering concepts. Its primary identity lay in polymer science, but its research ranged from biomacromolecular systems for medical purposes to environmentally relevant polymer questions. The biomedical importance of polymer research is considerable. Drug delivery, wound healing, tissue scaffolds, injectable hydrogels, implants, regenerative medicine, and bioresponsive materials all depend on sophisticated macromolecular design. The institute's work on injectable biodegradable hydrogels for minimally invasive tissue repair shows how materials science can enter medical thinking. Such research is translational in a distinctive way. It does not begin with a disease mechanism alone, but with the design of materials that can interact with biological systems. This requires cooperation between chemists, biologists, physicians, engineers, and regulatory specialists. The Institute of Macromolecular Chemistry therefore broadened the Academy's biomedical profile beyond genes, cells, and drugs. It showed that medical innovation may also arise from materials capable of supporting, replacing, repairing, or modulating living tissues (*Institute of Macromolecular Chemistry of the CAS, n.d.*; *Institute of Macromolecular Chemistry of the CAS, n.d.*).

The emergence of European translational infrastructures gave these national developments a wider framework. EATRIS, the European infrastructure for translational medicine, defines its mission through helping research communities translate scientific discoveries into benefits for patients. EATRIS-CZ connected Czech biomedical, chemical, clinical, and academic institutions in a national node embedded in the wider European infrastructure. Its purpose was to support movement along the translational value chain, including technologies, services, patient cohorts, clinical expertise, and multidisciplinary development. For the Academy, participation in such environments was highly significant. It placed CAS institutes within a European system that recognised the gap between discovery and clinical application as an institutional problem, not merely a scientific one. Many promising findings fail not because they are intellectually weak, but because they lack validation, regulatory strategy, clinical connection, reproducibility, or development support. EATRIS-type infrastructures therefore helped define translation as an organised process. Academy institutes could contribute basic discoveries, platforms, models, imaging, chemistry, biomaterials, or disease mechanisms, while the wider infrastructure linked these contributions to clinical and developmental pathways. This was a mature form of translational thinking, far beyond the simplistic idea that application follows automatically from discovery (*EATRIS, n.d.*; *EATRIS-CZ, n.d.*; *Research Infrastructures of the Czech Republic, n.d.*).

Research infrastructures also changed the internal social organisation of biomedical science. In earlier periods, an institute's prestige might have centred mainly on leading scientists,

departments, and publications. After 1993, and especially after the 2000s, facilities, platforms, and service units became central to biomedical productivity. Imaging, flow cytometry, mass spectrometry, sequencing, phenotyping, animal models, structural biology, bioinformatics, chemical screening, and biomaterial characterisation require specialised personnel and professional management. These infrastructures are not secondary to science; they shape what questions can be asked. A laboratory with access to advanced imaging can study cellular processes differently from one without such access. A group with phenogenomics capacity can move from gene association to functional organismal evidence. A chemist with screening support can develop biological probes more systematically. The Academy's biomedical institutes therefore became more collective and more technically layered. The rise of infrastructures also changed careers. Facility scientists, technicians, data experts, animal-care specialists, imaging specialists, and project managers became indispensable actors in translational potential. This transformation made biomedical research less dependent on isolated laboratory heroism and more dependent on institutional ecosystems (*Czech-BioImaging, n.d.*; *INFRAFRONTIER, n.d.*; *CZ-OPENSCREEN, n.d.*).

The relationship between Academy biomedical institutes and universities became increasingly important in this context. Under the older Czechoslovak model, the Academy and universities had often been separated functionally: the Academy was oriented towards research, while universities carried the primary educational mission. After 1993, especially in biomedicine, this separation became less sustainable. Doctoral students needed access to advanced facilities and research groups. Academy scientists needed links to medical faculties, hospitals, and clinical questions. Universities needed strong research environments in which students could be trained at international levels. BIOCEV, EATRIS-CZ, Czech-BioImaging, and many doctoral collaborations all reflected this convergence. The Academy's biomedical institutes did not become teaching universities, but they became deeply involved in the formation of scientific careers. This was essential for translational potential because translation depends on people who can move between disciplines and institutions. A young researcher trained in an Academy laboratory and linked to a medical faculty may understand both molecular mechanisms and clinical relevance. Such hybrid training was one of the most important forms of renewal after 1993. It helped create a biomedical community that was not confined to inherited institutional borders (*BIOCEV, n.d.*; *Institute of Experimental Medicine of the CAS, n.d.*).

The Academy's biomedical institutes also had to navigate a changing ethical environment. Biomedical research touches the body, disease, ageing, disability, reproduction, animal experimentation, environmental exposure, genetic information, and potential human intervention. After 1993, the question of scientific freedom could not be understood only as liberation from political ideology. It also required responsible conduct, ethical review, data protection, animal welfare, informed consent where relevant, and careful public communication. Translational potential increases ethical responsibility because the closer research moves to diagnosis or therapy, the more directly it concerns patients and society. Preclinical models, stem-cell research, tissue engineering, toxicology, and genetic studies all require clear norms. The Academy's democratic legitimacy depended partly on its ability to sustain this responsible research culture. International integration reinforced this process because European projects and infrastructures impose standards for ethics, data, reproducibility, and governance. Biomedical autonomy therefore became conditional on accountability. This was not a contradiction. It was one of the defining features of modern public science: the freedom to pursue difficult questions within a framework that protects

human dignity, animal welfare, scientific integrity, and public trust (*EATRIS, n.d.*; *Czech Academy of Sciences, n.d.*).

The translational potential of Academy biomedicine must be distinguished from immediate medical delivery. This distinction is often misunderstood in public debates. A hospital treats patients; a biomedical institute may study the mechanisms that make future treatment possible. A company develops products; an Academy institute may discover the molecular target, model the disease, design the material, or validate the experimental system from which a product might eventually emerge. A ministry needs policy-relevant advice; researchers may provide evidence, but they cannot replace political decision-making. The Academy's role after 1993 was therefore intermediate and foundational. It occupied the difficult space between curiosity-driven research and potential social use. This position sometimes made its value less visible than that of hospitals or companies. Yet it was precisely this position that allowed long-term biomedical capacity to grow. If every project had been forced to promise immediate clinical outcomes, many of the strongest discoveries would never have begun. Conversely, if biomedical research had ignored application entirely, it would have lost contact with the health challenges of society. The Academy's post-1993 biomedical history is the history of maintaining this productive middle ground (*Institute of Experimental Medicine of the CAS, n.d.*; *Institute of Biotechnology of the Czech Academy of Sciences, n.d.*).

Ageing became one of the central themes linking biomedical institutes to public need. The Czech Republic, like most European societies, faced demographic ageing and the growing burden of chronic, degenerative, and non-infectious diseases. This context gave special importance to research on neurodegeneration, sensory loss, musculoskeletal disorders, cancer, metabolism, cardiovascular disease, tissue degeneration, and regenerative approaches. The Institute of Experimental Medicine's focus on diseases associated with ageing and the Institute of Physiology's emphasis on non-infectious diseases reflected this societal background. Ageing is not a single disease, but a biological and social condition that transforms medical systems. It requires research on cells, tissues, organs, inflammation, metabolism, environment, genetics, and repair mechanisms. The Academy's biomedical institutes could contribute because they were not restricted to one clinical specialty. They could study ageing as a set of mechanisms crossing neuroscience, toxicology, cancer biology, tissue engineering, physiology, and molecular genetics. This integrative capacity was one of the advantages of the Academy model. It made possible long-term research on conditions whose causes and consequences are distributed across biological scales (*Institute of Experimental Medicine of the CAS, n.d.*; *Institute of Physiology of the Czech Academy of Sciences, n.d.*).

Cancer research formed another field in which Academy biomedical institutes had strong translational potential. Cancer is a molecular, cellular, tissue-level, systemic, and environmental problem at once. It involves genome instability, DNA repair, cell-cycle control, signalling, metabolism, immune response, tissue microenvironment, environmental carcinogens, and therapeutic resistance. Academy institutes contributed to cancer-related research from several directions. Molecular genetics provided insight into cell-cycle checkpoints, DNA damage responses, tumour suppressors, and genome regulation. Biophysics contributed to DNA and chromatin mechanisms, radiation response, and molecular pharmacology. Experimental medicine addressed cancer biology, toxicology, pathology, and biomarkers. Organic chemistry and biochemistry contributed medicinal chemistry, bioactive compounds, and drug-discovery traditions. Biotechnology and screening

infrastructures supported molecular tools and potential therapeutic strategies. This distributed structure shows why the Academy's biomedical contribution cannot be reduced to a single cancer institute. Instead, cancer research emerged from a network of institutes whose different competencies converged on disease mechanisms. Such convergence is typical of modern translational biomedicine (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Institute of Experimental Medicine of the CAS, n.d.*; *Institute of Organic Chemistry and Biochemistry of the CAS, n.d.*).

Neuroscience and regenerative medicine also became important areas of biomedical promise. The Institute of Experimental Medicine's work in neurobiology, neurophysiology, neuropathology, stem cells, nervous tissue regeneration, and tissue replacement connected Czech Academy research to international debates about trauma, degeneration, repair, and functional recovery. These topics are medically urgent but scientifically difficult. The nervous system is complex, developmentally specialised, and limited in its regenerative capacity. Promising therapeutic strategies often require cell biology, biomaterials, animal models, electrophysiology, imaging, molecular markers, and careful preclinical validation. The Academy's strength lay in providing a research environment where such interdisciplinary work could be sustained without immediate clinical pressure. Regenerative medicine also connected the Institute of Experimental Medicine with materials science, including hydrogels and scaffolds developed in polymer research. This illustrates the wider Academy pattern: translational potential often appears when institutes outside a narrow biomedical category interact. A biological question may require a chemical material; a medical problem may require a physical imaging method; a therapeutic idea may require a genetic model. The Academy's institutional diversity therefore became a translational advantage (*Institute of Experimental Medicine of the CAS, n.d.*; *Institute of Macromolecular Chemistry of the CAS, n.d.*).

Environmental health formed a further bridge between biomedical and ecological thinking. The Institute of Experimental Medicine's attention to environmental pollution and human health demonstrates that biomedicine after 1993 was not limited to internal mechanisms of the body. It also had to address the biological consequences of external exposures. This was historically important in the Czech context because the late socialist period left severe environmental burdens, and the democratic period brought more open discussion of pollution, risk, and public health. Genetic toxicology, nanotoxicology, molecular epidemiology, and environmental medicine connected laboratory research with societal conditions. They showed that disease cannot be understood only as a private biological event. It may reflect air quality, chemicals, occupational exposure, food, water, nanoparticles, lifestyle, and regulatory choices. This broadened the Academy's biomedical mission. It made biomedical research part of a larger public-health ecology, linking cells and molecules to environmental policy. Translational potential in this area does not necessarily mean a drug. It may mean biomarkers of exposure, risk assessment, diagnostic markers, safer materials, or evidence supporting preventive policy. Such forms of translation are less spectacular than new therapies, but they are essential for public health (*Institute of Experimental Medicine of the CAS, n.d.*).

The post-1993 biomedical Academy also increasingly interacted with industry, but this interaction was selective and mediated by institutional safeguards. The most successful cases, such as IOCB's cooperation with Gilead, demonstrated the value of long-term partnership between excellent public research and a capable pharmaceutical company. Yet industry collaboration also raised questions about intellectual property, public interest, academic freedom, conflicts of interest, and distribution of benefits. The Academy had to

develop professional technology-transfer capacity precisely because informal arrangements were insufficient for modern biomedical innovation. Licensing agreements, start-up support, patent protection, and investor relations require expertise that scientists themselves often do not possess. At the same time, the Academy's public character meant that commercialisation could not become its sole mission. The goal was not to turn institutes into companies, but to create pathways through which socially valuable discoveries could move beyond the laboratory when appropriate. This balance was one of the most delicate aspects of post-1993 biomedical renewal. Too little transfer would waste potential; too much commercial pressure could distort scientific priorities. The Academy's evolving transfer structures attempted to hold these pressures in a workable equilibrium (*Institute of Organic Chemistry and Biochemistry of the CAS, 2017*; *Academy of Sciences of the Czech Republic, 2024*).

Internationalisation strengthened biomedical translational potential in several ways. It gave Czech researchers access to European projects, shared infrastructures, expert networks, mobility, industrial contacts, and international standards of validation. It also exposed institutes to competition and comparison. A biomedical discovery is rarely judged only within national borders. Diagnostic markers, therapeutic targets, disease models, biomaterials, and compounds must be credible to international peer communities. European infrastructures such as EATRIS, Euro-BioImaging, Czech-BioImaging, Instruct-ERIC-related structural biology, and INFRAFRONTIER-style model-organism systems helped align Czech biomedical research with this wider environment. This international embedding was essential for translation because medical innovation requires compatibility: data, protocols, models, ethics, regulation, and quality control must be understandable beyond one institute. The Academy's participation in these networks therefore increased the credibility and usability of Czech biomedical results. It also helped prevent isolation. In a small research system, the danger is not only lack of money, but lack of scale. International networks expanded the scale on which Czech biomedical institutes could operate (*EATRIS, n.d.*; *Czech-BioImaging, n.d.*; *INFRAFRONTIER, n.d.*).

The development of biomedical institutes after 1993 also changed the Academy's public image. Earlier public perceptions of an academy of sciences often centred on abstract scholarship, national prestige, or elite intellectual culture. Biomedical research gave the Academy a more direct connection with everyday concerns: ageing parents, cancer, neurodegeneration, infertility, environmental exposure, diabetes, viral disease, chronic illness, tissue damage, and future therapies. This public visibility was valuable, but it also required caution. Biomedical research can easily generate exaggerated hope, especially when media language turns early experimental findings into implied cures. Academy institutes therefore had to communicate both promise and uncertainty. Translational potential is not the same as guaranteed treatment. A biomarker may fail validation; a model may not predict human response; a compound may be toxic; a material may require years of testing. Responsible communication became part of biomedical professionalism. The Academy's authority depended on explaining why long-term research matters without overstating what it can immediately deliver. This communicative maturity was a significant element of post-socialist public science (*Institute of Experimental Medicine of the CAS, n.d.*; *Institute of Physiology of the Czech Academy of Sciences, n.d.*).

By the 2020s, the Academy's biomedical institutes had become embedded in a multi-centre national ecosystem. Prague-Krč, Dejvice, Vestec, Brno, Liběchov, Třeboň, České Budějovice, and other locations all contributed to the wider biomedical and life-science map. This

geography mattered because translational potential rarely emerges from one building. It grows from interactions among institutes, universities, hospitals, infrastructures, companies, and public agencies. The Academy's biomedical sector was therefore not a vertical hierarchy but a network. Some institutes focused on mechanisms of disease; others on molecules, microbes, materials, animals, physiology, or technologies. Some were deeply involved in European infrastructures; others maintained specialised expertise with long-term value. Together, they formed a biomedical capacity that was more diverse than any single institute could be. This diversity also protected the Academy from excessive dependence on one fashionable field. Biomedical science changes rapidly, and not every promising direction succeeds. A broad institutional ecology allows risk to be distributed and creativity to emerge from unexpected intersections. The Academy's post-1993 biomedical strength lay precisely in this diversity of methods, scales, and institutional histories (*Czech Academy of Sciences, 2026*).

The broader historical meaning of biomedical research after 1993 lies in its demonstration that the Academy could respond to societal needs without surrendering its identity as a fundamental research institution. This was not self-evident. In many post-socialist countries, research institutions faced pressure either to commercialise rapidly or to defend old structures without sufficient reform. The Czech Academy's biomedical institutes followed a more complex path. They restructured governance, entered competitive funding systems, built infrastructures, cooperated with universities, strengthened technology transfer, and joined European networks. Yet they also preserved the long-term logic of basic research. This combination allowed them to produce translational potential rather than only short-term application. The distinction is important. Application is a result; potential is a capacity. The Academy built capacity: people, laboratories, models, technologies, knowledge, intellectual property structures, and partnerships. Such capacity cannot be created overnight during a crisis or after a policy decision. It must be cultivated over decades. Biomedical research after 1993 therefore became one of the clearest arguments for why a democratic state needs a strong public academy (*Czech Academy of Sciences, n.d.*; *EATRIS-CZ, n.d.*).

Thus, biomedical institutes and translational potential after 1993 reveal one of the most important dimensions of the Czech Academy's modernisation. The Academy did not transform itself into a clinical provider or an industrial research corporation, but it created and renewed institutes capable of producing the mechanisms, models, materials, compounds, infrastructures, and expertise from which future diagnostics and therapies may arise. The Institute of Experimental Medicine, Institute of Physiology, Institute of Biotechnology, Institute of Molecular Genetics, Institute of Microbiology, Institute of Biophysics, Institute of Macromolecular Chemistry, Institute of Organic Chemistry and Biochemistry, and related centres such as BIOCEV, EATRIS-CZ, Czech-BioImaging, CZ-OPENSCREEN, and the Czech Centre for Phenogenomics together formed a network of fundamental biomedical capacity with translational horizons. Their history shows that the boundary between basic and applied research became more permeable but did not disappear. The Academy's strength lay in maintaining the autonomy required for deep discovery while building the partnerships, infrastructures, and transfer mechanisms needed for social usefulness. In this sense, biomedical research after 1993 became a condensed expression of the Academy's post-socialist institutional identity: historically continuous, scientifically ambitious, publicly accountable, internationally connected, and open to the long and uncertain path from knowledge to medical benefit.

2. Disease Research, Diagnostics, and Therapeutic Perspectives

After 1993, disease research within the Academy of Sciences of the Czech Republic developed as one of the most important bridges between fundamental biology and the practical expectations of a democratic society. The Academy did not become a hospital system, and its biomedical institutes did not replace clinical departments, medical faculties, or public-health authorities. Yet they increasingly worked on questions without which modern diagnostics and therapy cannot advance: how diseases begin, how cells respond to damage, how tissues degenerate or repair themselves, how pathogens interact with hosts, how genetic variation affects function, how environmental exposure leaves molecular traces, and how chemical compounds or biomaterials might intervene in pathological processes. This gave Academy biomedical research a distinctive position. It was upstream from treatment, but not detached from medical reality. Its task was to produce mechanisms, models, markers, tools, and experimental systems that could later be used by clinicians, hospitals, companies, or translational infrastructures. Disease research after 1993 therefore became a field in which scientific autonomy and social responsibility were constantly negotiated. On the one hand, the Academy had to protect slow, curiosity-driven research into basic biological mechanisms. On the other hand, public expectations increasingly asked why such research mattered for cancer, neurodegeneration, cardiovascular disease, infection, metabolic disorders, tissue injury, environmental health, and ageing. The answer lay not in a simple promise of rapid cures, but in the creation of a sustained biomedical capacity able to connect molecular knowledge with diagnostic and therapeutic horizons (*Institute of Experimental Medicine of the CAS, n.d.*; *Institute of Physiology of the Czech Academy of Sciences, n.d.*).

The post-1993 period changed the meaning of disease research because medicine itself was being transformed by molecular biology, genomics, imaging, bioinformatics, pharmacology, biomaterials, and preclinical modelling. Older medical research could often be organised around organs, symptoms, pathogens, or clinical categories. Modern biomedical research increasingly asked what molecular pathways, cellular states, regulatory circuits, immune responses, metabolic processes, and environmental exposures stood behind those categories. This shift suited the Academy's institutional profile. Its institutes were not designed for routine treatment, but they were well equipped to explore mechanisms. The Institute of Molecular Genetics could study genome integrity, immune regulation, cancer biology, cell signalling, and disease models. The Institute of Physiology could analyse normal and pathological functions across cells, tissues, organs, and whole organisms. The Institute of Experimental Medicine could connect neurobiology, cancer, stem cells, toxicology, tissue replacement, environmental health, and diagnostic markers. The Institute of Microbiology could address infection, immunity, microbial metabolites, and host-microbe interactions. The Institute of Biophysics could study DNA, chromatin, radiation effects, molecular structures, and cellular responses. The Institute of Organic Chemistry and Biochemistry could contribute medicinal chemistry and antiviral compounds. Disease research therefore emerged not from one single medical institute, but from a distributed Academy ecology of biological, chemical, physical, and biomedical expertise (*Czech Academy of Sciences, 2026*; *Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*).

Diagnostics became one of the areas in which the Academy's basic research could acquire visible medical relevance. A diagnostic marker is not merely a laboratory measurement. It is a bridge between hidden biological processes and clinical decision-making. To identify a useful marker, researchers must understand the disease mechanism, detect a measurable signal,

test its specificity and sensitivity, compare it with existing tools, and place it within a broader diagnostic workflow. The Institute of Experimental Medicine explicitly framed part of its biomedical mission around finding effective diagnostic markers and treatment strategies for serious diseases associated with ageing. This emphasis reflected a wider European problem. Ageing societies need earlier and more accurate detection of neurodegenerative disorders, cancer, musculoskeletal degeneration, sensory decline, ischaemic damage, and environmental injury. The Academy's contribution lay in studying the molecular and cellular events that precede visible clinical deterioration. Such work is not always spectacular because diagnostic research often advances through painstaking validation rather than dramatic discovery. Yet it is essential. Without reliable markers, medicine sees disease too late, treats it too generally, or misunderstands its progression. In this sense, the diagnostic dimension of Academy research placed fundamental biology directly inside the temporality of prevention and early intervention (*Institute of Experimental Medicine of the CAS, n.d.*).

The Institute of Physiology added another diagnostic dimension by focusing on the mechanisms of serious non-infectious diseases. This term includes some of the most important burdens of contemporary medicine: cardiovascular, metabolic, neurological, renal, and other chronic disorders. These diseases are often not caused by one pathogen or one simple genetic defect. They emerge from long interactions among physiology, metabolism, environment, behaviour, ageing, inflammation, and inherited predisposition. Such complexity makes them especially suitable for Academy research, because they require integrative biological thinking. The Institute of Physiology's work on basic mechanisms could contribute to prevention, diagnosis, and treatment precisely because chronic disease cannot be solved only at the bedside. It must be understood at the level of cellular energy, tissue regulation, signalling systems, organ communication, vascular function, neural control, and metabolic adaptation. This kind of research has translational potential, but its path to application is indirect. It clarifies what should be measured, which processes are causal, which are compensatory, and where intervention may be possible. The historical significance of physiology after 1993 lies in this bridging function. It preserved a classical discipline but turned it into a modern platform for understanding complex disease (*Institute of Physiology of the Czech Academy of Sciences, n.d.*; *Kopecký, 2015*).

Cancer research became one of the most important disease-oriented fields across Academy institutes. Cancer is not a single disease, but a family of pathological processes involving genome instability, cell-cycle control, DNA repair, oncogenes, tumour suppressors, metabolism, inflammation, immune surveillance, tissue microenvironment, and therapeutic resistance. This complexity made cancer research a natural meeting point for molecular genetics, biophysics, experimental medicine, organic chemistry, chemical biology, imaging, and preclinical modelling. The Institute of Molecular Genetics studied the molecular bases of serious diseases, including cancer and leukaemia, alongside immune mechanisms, DNA repair, cellular senescence, and the biology of normal and transformed cells. The Institute of Experimental Medicine contributed through molecular cancer biology, genetic toxicology, environmental health, and diagnostic markers. The Institute of Biophysics contributed through DNA and chromatin research, radiation biology, and cellular responses to damage. The Institute of Organic Chemistry and Biochemistry contributed through medicinal chemistry and compounds with therapeutic relevance. This distributed structure is historically important. It shows that modern cancer research inside the Academy did not develop as an isolated programme, but as a convergence of multiple disciplinary lineages. Such convergence

reflected the wider post-1993 transformation of Czech science from inherited institutes into networked biomedical capacity (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Institute of Experimental Medicine of the CAS, n.d.*; *Institute of Biophysics of the Czech Academy of Sciences, n.d.*).

DNA damage and repair became one of the conceptual bridges connecting cancer, ageing, immunological disease, neurodegeneration, and environmental exposure. Cells constantly encounter DNA damage from replication errors, radiation, chemical agents, oxidative stress, and other insults. If the damage is not repaired correctly, the consequences may include mutation, genome instability, cell death, senescence, malignancy, or tissue dysfunction. Academy institutes were well placed to study these processes because they possessed expertise in molecular genetics, biophysics, toxicology, cell biology, and cancer research. The significance of this work goes beyond oncology. Defective DNA repair can be understood as a biological crossroads where several disease processes meet. It helps explain why ageing tissues become more vulnerable, why cancer arises, why immune and neurological disorders may share molecular mechanisms, and why environmental exposures matter. In diagnostic terms, DNA damage and repair pathways may produce biomarkers of risk, exposure, or disease progression. In therapeutic terms, they may reveal vulnerabilities in tumour cells or guide strategies based on synthetic lethality. The Academy's research in this area therefore demonstrates how fundamental investigation of cellular maintenance can open multiple medical perspectives without being reducible to one clinical speciality (*Institute of Experimental Medicine of the CAS, 2025*; *Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*).

Neurodegenerative disease became another field in which Academy research connected mechanisms, diagnostics, and therapeutic hopes. Neurodegeneration is medically urgent because it affects ageing societies, family life, social care, and the economic sustainability of health systems. It is also scientifically difficult because neurons, glial cells, synapses, blood vessels, immune responses, protein aggregation, mitochondrial function, inflammation, and genetic background all interact over long periods. The Institute of Experimental Medicine's work on serious diseases associated with ageing included neurodegeneration, trauma, ischaemia, and sensory degeneration. The Institute of Animal Physiology and Genetics also contributed through animal models and biomarker-oriented research, including work relevant to neurodegenerative Huntington's disease. This field illustrates the Academy's distinctive biomedical role. It can develop models, study cellular and tissue mechanisms, test molecular hypotheses, investigate biomarkers, and explore regenerative or protective strategies. Yet it must also accept the slow and uncertain nature of translation. Neurodegenerative diseases have repeatedly disappointed premature therapeutic hopes. For that reason, the Academy's long-term mechanistic research is especially valuable. It provides the patient accumulation of knowledge needed before diagnostic and therapeutic breakthroughs become plausible (*Institute of Experimental Medicine of the CAS, n.d.*; *Institute of Animal Physiology and Genetics CAS, n.d.*).

Trauma, ischaemia, and tissue damage formed another important disease cluster. These conditions differ from chronic degeneration, but they also involve cellular stress, inflammation, vascular dysfunction, repair mechanisms, and limits of regeneration. Academy research in experimental medicine, physiology, biomaterials, and imaging contributed to understanding how tissues respond to injury and how repair might be supported. Ischaemia, for example, is not only a clinical event such as stroke or myocardial infarction. It is a biological

process involving oxygen deprivation, energy failure, oxidative stress, immune activation, cell death, and tissue remodelling. Trauma similarly requires understanding of neural, musculoskeletal, vascular, and cellular responses. The Academy's strength lay in studying these processes experimentally, often through models and controlled laboratory systems that make mechanism visible. Therapeutic perspectives in this area included neuroprotection, tissue replacement, biomaterials, stem-cell approaches, and improved diagnostic monitoring. These fields show why disease research cannot be separated from technologies of observation. Imaging, histology, molecular markers, electrophysiology, and animal models make injury and repair analysable. Without such tools, clinical medicine would see only the outcome, not the process (*Institute of Experimental Medicine of the CAS, n.d.*; *Czech-BioImaging, n.d.*).

Regenerative medicine and tissue engineering became especially important because they promised not only to treat symptoms but to repair or replace damaged biological structures. This promise required caution. Regenerative medicine is not a magical field of instant healing; it is a difficult intersection of cell biology, developmental biology, biomaterials, immunology, physiology, animal models, and clinical validation. The Institute of Experimental Medicine contributed through stem-cell research, tissue replacement, neurobiology, and pathology. The Institute of Macromolecular Chemistry contributed through biomaterials, polymer scaffolds, hydrogels, and bioanalogous systems for regenerative medicine and tissue engineering. These contributions show the interdisciplinary character of therapeutic perspectives inside the Academy. A cell-based strategy may fail without an appropriate material environment. A biomaterial may fail without understanding of cell behaviour, immune reaction, degradation, mechanical properties, and tissue integration. The Academy's institutional diversity allowed such problems to be approached from several directions. The historical significance of regenerative research lies less in immediate clinical success than in the creation of a research culture where biology and materials science could collaborate on repair as a scientific problem (*Institute of Experimental Medicine of the CAS, n.d.*; *Institute of Macromolecular Chemistry of the CAS, n.d.*).

Biomaterials broadened the meaning of therapy beyond drugs and genes. Modern medicine increasingly depends on materials that can support tissues, deliver compounds, modulate cell behaviour, replace damaged structures, or interact safely with the body. Hydrogels, polymer scaffolds, bioactive surfaces, injectable systems, and biodegradable materials belong to this world. The Institute of Macromolecular Chemistry's work on polymer biomaterials and functional interfaces aimed at supporting structures for regenerative medicine and tissue engineering demonstrates how a chemical institute could become part of biomedical innovation. This is important for the institutional history of the Academy because it shows that disease research was not confined to institutes formally labelled biomedical. Therapeutic perspectives could arise from chemistry, physics, materials science, and engineering-like approaches inside the Academy. Such work also reveals why translation is often non-linear. A material developed through polymer chemistry may become relevant to cartilage repair, wound healing, neural regeneration, drug delivery, or cell culture. Its clinical future depends on many steps, but without the initial materials science, the medical possibility would not exist. The Academy's biomedical potential was therefore distributed across disciplinary borders (*Institute of Macromolecular Chemistry of the CAS, n.d.*).

Infectious disease research and antiviral therapy represented a different but historically powerful line of Academy contribution. The work of Antonín Holý at the Institute of Organic

Chemistry and Biochemistry became one of the most internationally recognised examples of Czech science producing clinically important therapeutics. His research on acyclic nucleoside phosphonates, developed in cooperation with Erik De Clercq and later with Gilead Sciences, led to compounds including cidofovir, adefovir, and tenofovir, with major importance for antiviral treatment, especially HIV and hepatitis B therapy. This achievement is often celebrated as a success story of applied science, but historically it is more accurate to see it as a triumph of long-term basic synthetic and medicinal chemistry. The medically useful drugs emerged because fundamental work on modified nucleosides and nucleotides was pursued with persistence, creativity, and international collaboration. After 1993, this legacy shaped the Academy's understanding of therapeutic perspectives. It showed that public research can generate discoveries of global medical importance, but only when basic research, intellectual property, industrial partnership, and clinical development are connected over long periods. It also provided a powerful argument against reducing research value to short-term application. The path from compound to therapy was long, uncertain, and internationally networked (*Institute of Organic Chemistry and Biochemistry of the CAS, n.d.*; *Institute of Organic Chemistry and Biochemistry of the CAS, n.d.*).

The antiviral tradition also linked disease research to public-health preparedness. Viral diseases are biologically dynamic and socially disruptive. They require understanding of viral replication, host-cell interaction, immunity, molecular diagnostics, drug resistance, and epidemiological movement. The Institute of Microbiology, Institute of Molecular Genetics, Institute of Organic Chemistry and Biochemistry, and related infrastructures all contributed different capacities relevant to infection and antiviral response. This distributed knowledge became especially visible during the COVID-19 period, but its roots were older. Antiviral compounds, molecular virology, microbial immunology, and preclinical models existed before any particular crisis. That is precisely why they could become useful when a crisis came. In historical terms, infectious disease research shows that preparedness is not created during an emergency. It is the accumulated outcome of long-term investment in basic mechanisms, compounds, platforms, and trained personnel. The Academy's antiviral and microbiological research therefore belonged both to therapeutic science and to national resilience (*Institute of Organic Chemistry and Biochemistry of the CAS, n.d.*; *Institute of Microbiology of the Czech Academy of Sciences, n.d.*).

Microbiology contributed to disease research not only through pathogens, but also through immunity, microbiomes, microbial products, and biotechnology. Modern medicine increasingly recognises that microorganisms are not simply enemies. They may cause disease, protect against disease, produce useful molecules, shape immune development, influence metabolism, and participate in environmental exposure. The Institute of Microbiology's research profile, including microbial physiology, molecular and cellular microbiology, immunology, biotechnology, biosynthesis of natural products, and host-microbe interactions, therefore had broad diagnostic and therapeutic relevance. Natural products and microbial metabolites are especially important because many antibiotics, immunomodulators, and pharmacological tools have microbial origins. At the same time, understanding microbial pathogenesis and immune response can guide diagnostics, vaccines, and treatment strategies. The Academy's microbiological research after 1993 thus moved between fundamental organismal knowledge and future medical use. It also helped integrate infectious disease research with biotechnology and ecology. Microbes inhabit bodies, soils, waters, laboratories, and industrial systems. This made microbiology one of the most naturally

translational biological disciplines inside the Academy (*Institute of Microbiology of the Czech Academy of Sciences, n.d.*; *EATRIS-CZ, n.d.*).

Immunology formed another central bridge between disease mechanisms and therapeutic perspectives. The Academy's immunological traditions reached back to Czechoslovak experimental biology and immunogenetics, but after 1993 they operated within a much wider molecular and biomedical context. Immunology became relevant not only to infection, but also to cancer, transplantation, autoimmunity, allergy, inflammation, ageing, and regenerative medicine. The Institute of Molecular Genetics, Institute of Microbiology, Institute of Experimental Medicine, and other centres contributed to immune-related research from different directions. The therapeutic significance of immunology increased dramatically in the 21st century with the rise of immunotherapies, checkpoint inhibitors, monoclonal antibodies, and cell-based immune approaches. Academy research was not necessarily the clinical endpoint of these developments, but it contributed to the mechanistic knowledge from which such developments depend. Understanding immune recognition, tumour models, host defence, inflammatory regulation, and cellular communication is essential for future diagnostics and therapy. Immunology also illustrates a broader historical point. Fields that once belonged to basic experimental biology can later become central to medicine when technological and clinical circumstances change (*Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*; *Institute of Microbiology of the Czech Academy of Sciences, n.d.*).

Preclinical modelling became one of the most important conditions for moving from mechanism to therapy. A disease mechanism identified in cells or tissues often needs validation in living organisms before it can inform medical development. The Czech Centre for Phenogenomics provided a major national and European platform for this purpose, offering standardised assays, rodent disease models, phenotyping, imaging, metabolomics, genetic engineering, and other capacities. This changed the practical possibilities of Czech biomedical research. Individual laboratories no longer had to rely only on limited in-house animal models or improvised phenotyping. They could access professionalised infrastructures with quality control and international standards. Disease models are not perfect replicas of human conditions, and responsible scientists know their limits. Yet they remain indispensable for understanding gene function, testing hypotheses, studying systemic effects, and assessing potential interventions. Phenogenomics therefore created a bridge between molecular genetics and medical interpretation. In institutional terms, it also shifted the Academy towards a shared-service model in which specialised facilities support wider research communities. This was a major part of post-1993 biomedical modernisation (*Czech Centre for Phenogenomics, n.d.*; *INFRAFRONTIER, n.d.*).

Animal models also mattered beyond rodents. The Institute of Animal Physiology and Genetics studied domestic, wild, and laboratory animals across biomedical and biodiversity-oriented topics, including animal models of human disease, biomarkers, and therapeutic validation. Its work demonstrates that disease research can benefit from comparative biology. Different animal systems offer different insights into physiology, reproduction, development, neurodegeneration, immunity, and tissue function. Large animal models may sometimes approximate human physiology better than small rodents, while wild-derived or genetically diverse animals may reveal variation hidden by standard laboratory strains. This comparative perspective is institutionally important because it resists the narrowing of biomedicine to a few standardised models. Modern disease research needs standardisation, but it also needs biological diversity. The Institute of Animal Physiology and Genetics contributed to this balance

by connecting physiology, genetics, ecology, evolution, and biomedical modelling. Its position inside the Academy's biological-medical section thus broadened the meaning of translational research beyond human-centred laboratory systems alone (*Institute of Animal Physiology and Genetics CAS, n.d.*; *Institute of Animal Physiology and Genetics CAS, n.d.*).

Chemical biology and drug discovery infrastructures added another route from disease mechanism to therapeutic perspective. CZ-OPENSCREEN, hosted at the Institute of Molecular Genetics, provided open access to chemical biology and genetics tools, molecular probes, compound libraries, screening technologies, and candidates for potential therapeutic development. This infrastructure was important because early drug discovery is not simply the search for a medicine in the narrow sense. It begins with probes that help researchers understand biological pathways, validate targets, and manipulate cellular processes. A useful probe may never become a drug, but it can transform understanding of a disease mechanism. Conversely, some compounds may become proof-of-concept candidates for later therapeutic development. CZ-OPENSCREEN therefore occupied the early, exploratory end of the therapeutic pipeline. Its value lay in bringing chemistry, biology, informatics, assay design, and screening into a shared research environment. This was another sign that the Academy's post-1993 disease research was becoming infrastructural, interdisciplinary, and internationally compatible (*CZ-OPENSCREEN, n.d.*; *CZ-OPENSCREEN, 2026*).

Imaging technologies became essential for diagnosis-oriented and therapy-oriented research. Czech-BioImaging, as a distributed national infrastructure for biological and medical imaging, provided access to advanced imaging expertise, resources, services, image analysis, and training. The importance of imaging lies in its ability to visualise disease processes at multiple scales: molecules, organelles, cells, tissues, organs, animals, and sometimes humans. Imaging can reveal tumour growth, tissue damage, cellular migration, neural degeneration, vascular changes, protein localisation, organelle dynamics, and therapeutic responses. For Academy institutes, advanced imaging changed the epistemology of disease research. It allowed researchers to see processes that would otherwise remain inferred from indirect biochemical measurements. It also supported diagnostic development because many medical diagnostics depend on visualisation, contrast, resolution, and interpretation of images. The open-access character of Czech-BioImaging made such technologies available beyond one laboratory or institute. In this sense, imaging infrastructures turned observation into a national biomedical capacity. They also connected Czech disease research to European imaging standards and data practices (*Czech-BioImaging, n.d.*; *Institute of Molecular Genetics of the Czech Academy of Sciences, 2025*).

Bioinformatics and biological data systems similarly became indispensable for disease research. Genomics, transcriptomics, proteomics, metabolomics, imaging, phenotyping, and clinical-adjacent datasets generate quantities of information that cannot be interpreted by traditional laboratory intuition alone. Disease research after 1993 increasingly required computational expertise to identify patterns, biomarkers, variants, pathways, and correlations. The Institute of Molecular Genetics and related infrastructures such as ELIXIR CZ supported this transition. Bioinformatics helped move diagnosis from single markers towards multi-parameter signatures and systems-level interpretation. It also made research more reproducible and comparable when data standards were properly applied. In therapeutic research, computational analysis can help identify targets, predict compound effects, interpret model-organism phenotypes, and integrate molecular layers. The Academy's engagement with data-intensive biology therefore changed the practical meaning of

biomedical expertise. A modern disease researcher had to understand not only cells and tissues, but also datasets, algorithms, statistical uncertainty, and data stewardship. This was one of the clearest signs that biomedical research had entered the age of networked knowledge (*ELIXIR CZ, n.d.*; *Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*).

Environmental health research added a preventive dimension to diagnostics and therapy. The Institute of Experimental Medicine explicitly considered the impact of environmental pollution on human health, which placed disease research within a broader ecological and social frame. This was particularly relevant in the Czech lands, where industrial pollution, air quality, occupational exposure, and environmental transformation had long been important public concerns. Biomedical research on environmental exposure can produce diagnostic markers of damage, identify vulnerable populations, clarify mechanisms of toxicity, and support preventive policy. Nanotoxicology and genetic toxicology are important here because new materials and old pollutants alike may affect cells, DNA, immune systems, and organs in subtle ways. Prevention is sometimes less visible than therapy, but it may be more socially powerful. A diagnostic marker that reveals harmful exposure, or a mechanistic study that leads to safer regulation, may prevent disease before treatment is needed. The Academy's environmental biomedical research therefore broadened the meaning of medical benefit. It showed that disease research is not only about curing individuals after illness appears, but also about understanding and reducing the conditions that produce disease (*Institute of Experimental Medicine of the CAS, n.d.*).

Ageing provided a unifying framework for many disease areas. Cancer, neurodegeneration, musculoskeletal decline, sensory impairment, metabolic dysfunction, cardiovascular disease, and reduced regenerative capacity all become more common with age. The Institute of Experimental Medicine and Institute of Physiology both placed major emphasis on diseases associated with ageing or non-communicable disorders connected with ageing and obesity. This focus reflected both scientific and demographic realities. Ageing is not simply the passage of time. It is a biological process involving DNA damage, cellular senescence, mitochondrial dysfunction, inflammation, proteostasis, stem-cell exhaustion, tissue remodelling, and environmental interaction. Understanding ageing therefore requires the combined efforts of molecular biology, physiology, toxicology, neuroscience, oncology, and regenerative medicine. Diagnostic and therapeutic perspectives in this field include biomarkers of biological age, early detection of degeneration, interventions in inflammation or metabolism, tissue-repair strategies, and improved disease models. The Academy's strength lay in approaching ageing not as one disease, but as a biological context in which many diseases become possible. This integrative perspective made ageing one of the most important biomedical themes after 1993 (*Institute of Experimental Medicine of the CAS, n.d.*; *Institute of Physiology of the Czech Academy of Sciences, n.d.*).

The Academy's disease research also interacted with European translational infrastructures. EATRIS-CZ connected Czech biomedical, chemical, and clinical research with the aim of accelerating transfer into clinical practice. This mattered because the path from discovery to patient benefit is difficult and often fails between laboratory proof and clinical validation. Translational infrastructures help by providing access to preclinical and clinical expertise, development platforms, patient cohorts, regulatory knowledge, and multidisciplinary networks. For Academy institutes, EATRIS-CZ offered a framework in which basic discoveries could be positioned within a broader value chain. This did not mean that every Academy project

had to become a therapy. Rather, it meant that promising findings could be supported more systematically when they had translational potential. Such infrastructures also encouraged researchers to think earlier about validation, reproducibility, clinical relevance, and development pathways. In the institutional history of the Academy, this represented a maturation of the relationship between basic research and medicine. Translation was no longer left to chance or individual contacts; it became a recognised organisational problem requiring infrastructure (*EATRIS-CZ, n.d.*; *EATRIS, n.d.*).

Therapeutic perspectives also required intellectual-property management and professional technology transfer. The success of antiviral compounds from IOCB showed the importance of patents, licensing, and industrial development. After 1993, the Academy increasingly recognised that medical benefit often depends on arrangements outside the laboratory. A promising compound or biomaterial may disappear without legal protection, development funding, regulatory strategy, or industrial partner. The creation of technology-transfer structures, including i&i Prague, showed that Czech research institutions were learning to handle this complex terrain more professionally. This was especially important in disease research because therapies are expensive and risky to develop. Academic institutes can discover targets, compounds, materials, or mechanisms, but they usually cannot complete clinical development alone. Professional transfer structures therefore became part of the therapeutic ecosystem. At the same time, the Academy had to preserve its public mission. Commercialisation could support social benefit, but it could not become the only measure of scientific value. The historical challenge was to create pathways from discovery to application without distorting the exploratory character of Academy research (*Institute of Organic Chemistry and Biochemistry of the CAS, 2017*; *Academy of Sciences of the Czech Republic, 2024*).

The relation between diagnostics and therapy became increasingly intertwined. Earlier medical thinking often treated diagnosis as a preliminary step and therapy as a separate intervention. Modern biomedical research increasingly sees them as connected through mechanisms and biomarkers. A diagnostic marker may define a patient subgroup that responds to a particular therapy. A molecular pathway may serve both as a disease indicator and as a therapeutic target. Imaging may diagnose damage and monitor treatment response. Genetic models may reveal both disease cause and possible intervention point. Chemical probes may clarify a mechanism while suggesting drug candidates. Academy research after 1993 developed in exactly this interconnected environment. The Institute of Molecular Genetics, Czech Centre for Phenogenomics, Czech-BioImaging, CZ-OPENSCREEN, Institute of Experimental Medicine, Institute of Physiology, and IOCB all contributed to different points along this continuum. This is why the phrase “diagnostics and therapeutic perspectives” should be read as one historical development rather than two separate topics. The post-socialist biomedical Academy became a place where seeing disease, explaining disease, modelling disease, and imagining intervention increasingly belonged to the same research process (*Czech Centre for Phenogenomics, n.d.*; *Czech-BioImaging, n.d.*; *CZ-OPENSCREEN, n.d.*).

Disease research also reshaped the Academy’s relationship with patients and the public, even when institutes did not treat patients directly. Public interest in biomedical research is intense because disease touches personal life, fear, hope, ageing, family responsibility, and social vulnerability. This gave Academy biomedical communication a special ethical weight. Researchers had to explain why basic research on genes, cells, animals, compounds, or materials might matter for future medicine, while avoiding exaggerated promises. Therapeutic

perspectives are not therapies. A marker discovered in a laboratory is not automatically a diagnostic test. A compound active in cells is not automatically a medicine. A successful animal model is not automatically a cure for patients. The Academy's credibility depended on maintaining this distinction. At the same time, it had to communicate that long-term research is genuinely necessary for medical progress. This required a public language more careful than promotional rhetoric but more accessible than technical reports. Biomedical research after 1993 therefore contributed to a new democratic culture of science communication in which public trust depended on both ambition and restraint (*Institute of Experimental Medicine of the CAS, n.d.*; *Czech Academy of Sciences, n.d.*).

The institutional geography of disease research after 1993 was also important. Prague hosted major biomedical capacities in Krč, Dejvice, and Vestec, but Brno, Liběchov, and other sites also contributed. Brno's Institute of Biophysics, Liběchov's animal physiology and genetics traditions, and the broader network of Academy and university collaborations show that biomedical research was not confined to one metropolitan centre. This distributed geography mattered because disease research needs diverse infrastructures and forms of expertise. A medicinal chemistry success may arise in Prague; a biophysical mechanism may be studied in Brno; an animal model may be developed in Liběchov or Vestec; an imaging platform may connect several cities; a translational project may involve a hospital in Olomouc, Prague, or Brno. The Academy's biomedical system thus became a national network rather than a single institution. This was consistent with the broader post-1993 transformation of Czech science, in which research excellence depended on cooperation among institutes, universities, hospitals, infrastructures, and international partners. Disease research became a practical field in which this networked model was tested and strengthened (*Czech Academy of Sciences, 2026*; *Czech-BioImaging, n.d.*; *EATRIS-CZ, n.d.*).

The international dimension of disease research was unavoidable. Diseases do not respect national borders, and biomedical science advances through global comparison, shared models, international trials, compound development, and common standards. The antiviral success associated with Antonín Holý depended on international collaboration with Leuven and Gilead. EATRIS, Czech-BioImaging, INFRAFRONTIER, ELIXIR, and EU-OPENSCREEN-type environments placed Czech research within European infrastructures. Publication and peer review connected Academy laboratories to global communities studying cancer, neurodegeneration, infection, genomics, physiology, and materials. This internationalisation did not erase the Czech character of the Academy. Rather, it allowed Czech public research to contribute to global medical questions from its own institutional base. The historical meaning of disease research after 1993 therefore lies partly in this change of scale. A Czech institute could study a disease mechanism locally, but the result had to be interpretable internationally. A compound discovered in Prague could become a global medicine only through transnational development. A diagnostic or biomarker approach could become meaningful only if it met standards beyond one laboratory. This made international compatibility a condition of biomedical relevance (*Institute of Organic Chemistry and Biochemistry of the CAS, n.d.*; *EATRIS, n.d.*).

The post-1993 period also placed stronger emphasis on reproducibility, validation, and research integrity. Disease research is particularly vulnerable to premature claims because the desire for medical progress can be powerful. A finding that appears promising in one experimental system may fail in another. A biomarker may look useful in a small cohort but not in wider populations. A compound may show activity but lack safety, selectivity, or

pharmacological viability. Preclinical models may not adequately represent human disease. For this reason, the Academy's disease research needed robust methods, transparent reporting, standardised infrastructures, and ethical oversight. Czech Centre for Phenogenomics, Czech-BioImaging, CZ-OPENSCREEN, and EATRIS-CZ all contributed to this culture by offering standardised services and expertise. The issue was not merely technical. It was institutional and moral. Public research institutions must be reliable because society may build expectations, investments, and policies on their findings. The Academy's modern biomedical role therefore required not only discovery but disciplined validation. This was one of the major differences between mature translational potential and vague medical promise (*Czech Centre for Phenogenomics, n.d.*; *EATRIS-CZ, n.d.*).

By the 2020s, disease research in the Academy had become a multi-scale enterprise. It moved from molecules to cells, from cells to tissues, from tissues to organisms, from organisms to models of disease, from models to diagnostics, from diagnostics to therapeutic hypotheses, and from therapeutic hypotheses to possible translational pathways. This movement was rarely linear. Many projects remained fundamental; some produced tools; a few moved towards application; others changed understanding without immediate medical outcome. Yet the overall capacity was historically significant. The Academy had built an environment in which cancer, neurodegeneration, infection, ageing, chronic non-communicable disease, environmental exposure, tissue injury, and regenerative medicine could be approached through multiple methods and institutions. This was not the old academy model of isolated disciplinary excellence, nor the commercial model of product pipelines alone. It was a public research ecosystem capable of sustaining uncertainty. In disease research, such uncertainty is unavoidable. The Academy's value lay in making uncertainty productive rather than paralysing (*Czech Academy of Sciences, 2026*; *Institute of Experimental Medicine of the CAS, n.d.*).

Thus, disease research, diagnostics, and therapeutic perspectives after 1993 show how the Czech Academy's biomedical institutes transformed fundamental biological knowledge into a long-term medical capacity. The Academy did not promise immediate cures, and its strongest contribution was not routine clinical treatment. Its contribution lay in explaining mechanisms of disease, identifying possible diagnostic markers, developing animal and cellular models, creating imaging and phenotyping infrastructures, discovering chemical probes and antiviral compounds, designing biomaterials, studying environmental health, and connecting Czech research to European translational systems. Cancer, neurodegeneration, chronic non-infectious disease, infection, tissue damage, ageing, and toxic exposure became fields where disciplinary boundaries increasingly dissolved. Molecular genetics, physiology, experimental medicine, microbiology, biophysics, organic chemistry, polymer science, animal genetics, bioinformatics, and imaging all contributed to the same broad biomedical horizon. This history demonstrates that the Academy's post-1993 modernisation was not only administrative or institutional. It was also epistemic and social: the Academy learned to produce knowledge that remained fundamentally scientific while becoming increasingly meaningful for diagnosis, therapy, prevention, and public health.

3. The Academy during Public Health Crises

The COVID-19 pandemic placed the Academy of Sciences of the Czech Republic in a situation that was historically unusual but institutionally revealing. For decades, the Academy had

defended the value of long-term basic research, often against political impatience, economic utilitarianism, and the belief that knowledge should prove itself only through immediate application. The pandemic suddenly changed the terms of that public argument. Molecular biology, virology, immunology, aerosol science, modelling, data analysis, economics, sociology, psychology, ethics, materials research, and public communication became visibly relevant to the functioning of the state and the protection of society. The Academy did not become a ministry of health, a hospital network, or an emergency authority. Its role was different. It became a reservoir of expertise, equipment, trained personnel, laboratories, analytical capacity, public interpretation, and scientific credibility. This role had been built slowly through earlier institutional investments in molecular genetics, microbiology, biomedical research, chemical biology, imaging, informatics, social sciences, and technology transfer. A crisis made visible what normal times often conceal: the capacity to respond rapidly depends on institutions that have been maintained patiently before the emergency begins. The Academy's response to COVID-19 therefore belongs not only to the history of one pandemic, but to the wider institutional history of post-1993 Czech science. It showed how a democratic public research institution could move from autonomy to service without surrendering its scientific identity (*World Health Organization, 2023*; *Academy of Sciences of the Czech Republic, 2020*).

The global context of the crisis is essential for understanding the Academy's position. The World Health Organization declared COVID-19 a Public Health Emergency of International Concern on 30 January 2020 and characterised the outbreak as a pandemic on 11 March 2020. The emergency phase continued internationally until 5 May 2023, when the WHO Director-General accepted the recommendation to end the PHEIC while emphasising that COVID-19 remained a continuing health threat. These dates matter because they show that the crisis was not a short national disturbance, but a multi-year global event that reorganised science, government, education, work, social life, travel, medical logistics, and public trust. The Czech Academy's response unfolded inside this unstable international environment. Scientific knowledge changed quickly, variants emerged, public-health recommendations evolved, and political decisions had to be made under uncertainty. In such a context, the task of science was not to deliver absolute certainty, but to reduce uncertainty responsibly. For the Academy, this meant contributing where its capacities were strongest: testing, diagnostics, molecular analysis, modelling, materials expertise, social analysis, and public explanation. The pandemic thus revealed the practical meaning of the Academy's statutory mission to conduct research at an international level while considering the needs of Czech society. It was precisely the combination of international science and national responsibility that gave the Academy's contribution its historical importance (*World Health Organization, 2023*; *World Health Organization Regional Office for Europe, 2023*).

The first and most visible form of mobilisation was laboratory testing. In March 2020, when diagnostic capacity was a strategic bottleneck, several Academy institutes offered equipment, personnel, and expertise for SARS-CoV-2 detection. The Institute of Molecular Genetics received permission from the National Institute of Public Health to begin testing samples for the presence of the virus. BIOCEV, the joint centre of the Academy and Charles University, also received permission to conduct large-scale testing, with teams able to process hundreds of samples daily. The Biology Centre in České Budějovice, the ALGATECH Centre of the Institute of Microbiology in Třeboň, the Institute of Biophysics in Brno, and the Institute of Physiology through equipment support were all mentioned in early Academy communications. This

mobilisation was historically significant because it converted research infrastructure into emergency public-health capacity. Instruments and trained researchers normally used for molecular biology, plant virology, microbial research, or experimental analysis could be redirected towards urgent diagnostic work. The Academy did not replace clinical laboratories, but it extended the national testing network at a moment when capacity mattered. This showed that the boundary between fundamental research and public-health service could become permeable under crisis conditions. It also demonstrated that national preparedness depends on distributed scientific capacity, not only on formally medical institutions (*Academy of Sciences of the Czech Republic, 2020*; *Institute of Molecular Genetics of the Czech Academy of Sciences, 2020*).

The role of the Institute of Molecular Genetics was especially revealing. Its robotics station and high-throughput screening capacity allowed it to contribute to large-scale molecular testing, with public communications noting the possibility of testing up to one thousand samples per day. This capacity was not created for a pandemic. It had been developed as part of a modern molecular-biology and chemical-biology infrastructure. Yet when the crisis arrived, precisely that infrastructure became useful for public health. This is one of the clearest examples of how basic research institutions generate latent emergency capacity. A robotics platform may appear remote from everyday medical care until a country suddenly needs rapid, reliable, scalable testing. The Institute of Molecular Genetics also stood at the intersection of several pandemic-relevant fields: molecular diagnostics, genomics, cell biology, immunology, bioinformatics, and research infrastructures such as CZ-OPENSCREEN. Its mobilisation therefore represented more than a technical contribution. It showed how the post-1993 investment in modern life-science platforms gave the Academy a capacity that could be redirected quickly when society needed it. In historical terms, the pandemic turned the molecularisation of Czech biology into a public-health asset (*Institute of Molecular Genetics of the Czech Academy of Sciences, 2020*; *ESFRI, 2020*).

BIOCEV became another important node of crisis response. As a biotechnology and biomedicine centre jointly developed by the Academy and Charles University, BIOCEV had already symbolised the post-1993 move towards shared infrastructures and institutional cooperation. During the pandemic, this cooperation became operational. Testing teams at BIOCEV involved virological and service laboratories of Charles University faculties together with the Institute of Biotechnology and the Institute of Molecular Genetics of the Czech Academy of Sciences. The coordinator was Ruth Tachezy from Charles University, which illustrates the collaborative rather than strictly hierarchical nature of the response. The centre's ability to process samples from hospitals and nursing homes showed that the Academy-university infrastructure could be connected directly to urgent social need. This was institutionally important because BIOCEV had sometimes been understood as a strategic research investment whose value would appear in publications, biotechnology, and doctoral training. COVID-19 added another dimension: crisis resilience. A shared biomedical centre could become a testing platform, a coordination space, and a bridge between academic science and the health system. The pandemic therefore validated the broader logic of integrated research infrastructures in a way that ordinary evaluation metrics might not capture (*BIOCEV Gene Core, 2020*; *Academy of Sciences of the Czech Republic, 2020*).

The Biology Centre CAS in České Budějovice also demonstrated the unexpected flexibility of biological expertise. Plant virologists and other researchers contributed to SARS-CoV-2 testing, even though their routine scientific work did not primarily concern human medicine.

This was not an accident. Virology, whether plant, animal, or human, depends on shared molecular principles and laboratory methods. Researchers trained to handle viral nucleic acids, amplification techniques, laboratory safety, and molecular detection can adapt when a new public-health need arises. The Biology Centre's involvement therefore showed that the Academy's organismal, ecological, and agricultural biological expertise also had crisis value. Public health is often imagined narrowly as a medical domain, but pandemic response depends on a wider biological culture. It requires people who understand viruses, molecular detection, host-pathogen systems, laboratory workflows, and data. The Biology Centre's contribution also underlined the decentralised geography of Czech scientific resilience. Testing and expertise were not limited to Prague; regional Academy capacities could support hospitals and public-health needs in South Bohemia and surrounding areas. This regional dimension is important in the institutional history of the Academy because it shows that scientific infrastructure outside the capital can become strategically important during national emergencies (*Academy of Sciences of the Czech Republic, 2020*; *Biology Centre CAS, n.d.*).

Diagnostics also became a field of rapid innovation. In the early phase of the pandemic, the Academy reported that researchers were working on simpler and more efficient methods that would allow faster testing of samples. IOCB Tech, the technology-transfer subsidiary of the Institute of Organic Chemistry and Biochemistry, donated CZK 7 million for research and development of new diagnostic tests for COVID-19, supporting teams at Charles University and the Institute of Molecular Genetics. This episode is historically important because it connected several themes of the Academy's post-1993 transformation: biomedical expertise, technology transfer, public responsibility, cooperation with universities, and rapid response to social need. Diagnostic innovation during a crisis does not arise only from scientific creativity. It requires funding, institutional trust, intellectual-property awareness, technical validation, and coordination with public-health authorities. The donation from IOCB Tech showed how technology-transfer structures developed in the post-socialist period could serve not only commercialisation but also emergency research. It also indicated that the Academy's strongest response was not confined to one institute. It emerged from a network of institutes, university laboratories, transfer offices, and scientific leaders capable of redirecting resources quickly (*Academy of Sciences of the Czech Republic, 2020*; *Institute of Molecular Genetics of the Czech Academy of Sciences, 2020*).

The pandemic also highlighted the importance of antiviral research traditions associated with the Institute of Organic Chemistry and Biochemistry. The institute's earlier success in antiviral chemistry, especially through the work of Antonín Holý and later international collaborations, gave Czech science a historically strong symbolic position in the field of antiviral therapeutics. During COVID-19, public attention often turned to remdesivir, developed by Gilead Sciences, where Tomáš Cihlář, a former student in the wider Czech antiviral tradition, played an important role. The Academy's early pandemic communications explicitly referred to this lineage when discussing medicines against viral infections. This should not be interpreted as a simple national claim over a global drug-development process. Rather, it reveals how scientific traditions can become publicly meaningful in moments of crisis. The history of Czech antiviral chemistry gave the Academy credibility when society was looking for expert interpretation of possible treatments. It also reminded policymakers that therapeutic capacity is not created instantly when a new virus appears. It grows out of decades of organic chemistry, biochemistry, molecular virology, pharmacology, industrial partnership, and international collaboration. The pandemic therefore reinforced one of the central lessons of Academy biomedical history: long-

term basic research is a form of preparedness (*Academy of Sciences of the Czech Republic, 2020*; *Institute of Organic Chemistry and Biochemistry of the CAS, n.d.*).

The Academy's response was not limited to testing and diagnostics. Materials research became crucial because the early pandemic involved severe shortages of masks, respirators, filters, and protective equipment. Experts from the Institute of Chemical Process Fundamentals tested materials for protective gear using aerosol-measurement expertise developed before the crisis. Their work concerned the ability of materials to stop aerosol particles in the size range relevant to viral transmission. This contribution is important because it broadens the meaning of public-health science. A respiratory pandemic is not only a problem of virology or medicine; it is also a problem of aerosols, filtration, material structure, air flow, occupational safety, manufacturing, and public behaviour. The Academy's technical and chemical institutes could therefore contribute to health protection even though they were not biomedical institutes in the narrow sense. This illustrates one of the main institutional features of the Academy: its disciplinary breadth allows cross-domain responses. The same organisation that studies molecules, cells, fossils, social behaviour, plasma, materials, and economics can mobilise different forms of expertise when a crisis crosses disciplinary boundaries. COVID-19 showed that public health is a system problem, and the Academy's multidisciplinary structure was well suited to such a problem (*Academy of Sciences of the Czech Republic, 2020*).

The pandemic also brought modelling and data analysis to the centre of public debate. Epidemiological curves, reproduction numbers, scenarios, hospital-capacity projections, and behavioural responses became part of everyday political language. The Academy's Institute of Computer Science, Institute of Information Theory and Automation, Institute of Organic Chemistry and Biochemistry, and the IDEA think tank at CERGE-EI participated in modelling and analytical initiatives, including the Model antiCOVID-19 Initiative. Such work demonstrated that a public-health crisis is not only biological. It is also mathematical, computational, economic, and social. Models cannot decide policy by themselves, but they can make possible futures visible. They can compare scenarios, identify trade-offs, and expose the consequences of delay or relaxation. At the same time, modelling during a crisis is uncertain and politically sensitive. Data may be incomplete, public behaviour may change, and policymakers may demand more certainty than science can provide. The Academy's contribution in this area therefore involved not only technical modelling, but also the public practice of explaining uncertainty. This was a new form of scientific authority: not the authority of final answers, but the authority of disciplined, transparent, and revisable analysis (*Academy of Sciences of the Czech Republic, 2020*; *Sherratt et al., 2023*).

The social sciences within the Academy also played a significant role. The pandemic was a biological event, but it became a social crisis because it disrupted schools, workplaces, households, inequalities, trust, communication, mobility, and public behaviour. The IDEA think tank analysed the economic shock, labour-market risks, household difficulties, remote education, and social consequences of containment measures. Researchers from the Institute of Sociology and related institutions examined health, quality of life, and social disadvantage. The Centre for Values in Science and Technology and other humanities and social-science actors addressed ethical questions connected with epidemic response. This interdisciplinary response matters for the history of the Academy because it shows that public health cannot be reduced to biomedical expertise. A scientifically correct recommendation may fail if people do not trust institutions, cannot afford to comply, lack information, or

experience measures as unfair. During COVID-19, the Academy's value lay partly in its capacity to combine laboratory science with analysis of society. This reflected the broader post-1993 institutional identity of CAS as a multi-disciplinary academy rather than a narrowly technical research agency (*Academy of Sciences of the Czech Republic, 2020*; *Bartoš et al., 2022*).

Vaccine communication became one of the clearest examples of the interaction between public health, behavioural science, and trust. A study involving researchers from CERGE-EI, the joint workplace of Charles University and the Economics Institute of the Czech Academy of Sciences, found that many people underestimated physicians' support for COVID-19 vaccination. Communicating the broad consensus among doctors increased vaccination uptake. This finding is important because it shows that public-health crises are also crises of perception. The availability of vaccines or scientific evidence does not automatically produce acceptance. People interpret risk through trust, social norms, identity, misinformation, and perceived expert disagreement. The Academy's contribution here did not take the form of a vaccine or diagnostic test, but of behavioural knowledge that could improve public-health outcomes. Such work belongs fully to the history of the Academy during crisis because it demonstrates that scientific expertise can intervene in the social conditions of health. It also shows why the Academy's multidisciplinary structure mattered: economists and behavioural scientists could contribute to vaccination policy just as molecular biologists contributed to testing. Public health required both laboratory capacity and social understanding (*Academy of Sciences of the Czech Republic, 2022*; *Bartoš et al., 2022*).

Molecular surveillance became an increasingly important phase of the pandemic response after the first emergency wave. Initial testing answers the question of whether a person is infected. Genomic surveillance answers a different question: how the virus is changing, which variants are circulating, how transmission is evolving, and whether diagnostic, vaccine, or therapeutic strategies may need adjustment. In 2021, the Czech COVID-19 Genomics Consortium was established to coordinate a national SARS-CoV-2 molecular surveillance network. Researchers associated with the Institute of Molecular Genetics of the Czech Academy of Sciences were among those involved in the wider surveillance ecosystem. This development is significant because it shows how pandemic response matured from emergency detection to long-term genomic monitoring. It also connects directly with the post-1993 history of Czech molecular biology and bioinformatics. Without sequencing capacity, data infrastructure, trained personnel, and international comparison, variant surveillance would not have been possible. Molecular surveillance made the Academy's scientific networks part of the state's capacity to see viral evolution in real time. It also linked Czech data to global variant-tracking systems, showing that national public health depends on international data exchange (*Šúri et al., 2025*; *ECDC, 2023*).

The public commentary of Academy scientists on variants, including Omicron subvariants such as BA.5, also became part of crisis response. Jan Pačes from the Institute of Molecular Genetics explained why BA.5 spread effectively, including its ability to evade immunity acquired from previous variants. Such expert communication performed an important public function. It helped citizens understand why infection waves could occur even after vaccination campaigns, previous infection, or seasonal expectations. It also translated evolutionary biology into public language. Viral mutation, immune escape, variant replacement, and population immunity are complex concepts, but they became necessary for interpreting everyday life. The Academy's role here was not only to generate data but to narrate scientific meaning responsibly. This is historically important because post-socialist scientific authority

could no longer rest on institutional hierarchy alone. It had to be earned through clarity, credibility, and public engagement. Pandemic communication turned Academy scientists into visible interpreters of a changing biological reality (*Academy of Sciences of the Czech Republic, 2022*; *Šúri et al., 2025*).

The crisis also demonstrated the importance of European and international research infrastructures. CZ-OPENSCREEN, hosted by the Institute of Molecular Genetics and linked to EU-OPENSCREEN, was listed among research infrastructures mobilised against COVID-19, with plans for substantial testing capacity. EATRIS, ELIXIR, imaging networks, genomic consortia, and other infrastructures across Europe contributed to the broader pandemic research environment. This matters because COVID-19 was not a crisis that any national science system could solve alone. Methods, sequences, protocols, variants, preprints, clinical-trial results, vaccine data, and therapeutic information moved rapidly across borders. Czech Academy institutes participated in this international circulation from a national institutional base. The lesson is not that national science became irrelevant, but that national science had to be networked in order to be useful. Research infrastructures made that networking practical. They provided shared standards, equipment, data systems, access models, and professional communities. The Academy's earlier investment in infrastructures therefore became one of the hidden conditions of crisis response (*ESFRI, 2020*; *European Medicines Agency, 2023*).

Technology transfer acquired a distinctive crisis meaning during the pandemic. In normal times, technology transfer is often discussed in terms of patents, licensing, start-ups, and economic competitiveness. During a public-health emergency, the same structures can help move diagnostic tools, compounds, devices, or expertise towards urgent social use. IOCB Tech's support for diagnostic-test development is one example. The broader Czech innovation ecosystem also produced emergency medical technologies, such as ventilator development initiatives, though not all belonged directly to CAS. The Academy's relevance lay in its ability to connect knowledge, credibility, and transfer mechanisms. The crisis revealed that intellectual property and rapid mobilisation must be handled carefully. Excessive proprietary control can slow emergency response, but absence of professional transfer capacity can also prevent promising tools from reaching users. Post-1993 technology-transfer structures gave Czech Academy science a more mature way to navigate this terrain. They allowed the Academy to serve public need without abandoning the legal and developmental realities of biomedical innovation (*Institute of Molecular Genetics of the Czech Academy of Sciences, 2020*; *Institute of Organic Chemistry and Biochemistry of the CAS, 2021*).

The Academy's role during COVID-19 should also be understood as part of the history of public trust. In a pandemic, scientific institutions do not communicate into a vacuum. They speak into societies marked by fear, misinformation, political polarisation, economic anxiety, fatigue, and unequal exposure to risk. Scientific advice may be accepted, contested, selectively interpreted, or turned into political symbolism. The Academy therefore had to sustain credibility in a difficult communication environment. Its strongest position was not to act as a partisan actor, but to provide evidence, explain uncertainty, and correct misconceptions. This was especially important in matters such as testing, variants, vaccination, aerosol transmission, protective equipment, and social restrictions. Trust in science was not merely an abstract cultural value; it affected health behaviour and policy compliance. The Academy's public communication during COVID-19 continued a broader post-1989 transformation in which scientific authority had to become democratic rather than paternalistic. Scientists could

no longer speak as representatives of a state ideology. They had to speak as accountable experts in a plural society (*Bartoš et al., 2022*; *Academy of Sciences of the Czech Republic, 2022*).

The educational dimension of the crisis also involved the Academy. During lockdowns and school closures, CAS popularisers and institutes created or gathered online science materials for children, parents, and the public. This may appear secondary compared with testing or diagnostics, but it belongs to the wider public-health story because isolation, school disruption, and loss of structured learning were themselves social consequences of the pandemic. Science communication at home helped maintain a connection between public life and knowledge at a time when ordinary educational institutions were disrupted. The Academy's initiative also showed that public service during crisis can take many forms. It can mean testing samples, analysing filters, modelling epidemiological scenarios, advising on economic consequences, explaining vaccination, or offering educational resources. Such breadth is characteristic of an academy rather than a specialised biomedical agency. It reflects the idea that a public research institution serves society not only through direct technical outputs but also through intellectual continuity, public culture, and support for learning under abnormal conditions (*Academy of Sciences of the Czech Republic, 2020*).

The pandemic exposed both strengths and limitations of the Academy model. Its strengths were clear: deep expertise, disciplinary breadth, modern infrastructures, long-term laboratories, international networks, and public credibility. Its limitations were also visible. The Academy could not itself coordinate the entire national response, impose public-health measures, run hospitals, manufacture all necessary supplies, or guarantee political coherence. Its role depended on cooperation with ministries, public-health authorities, universities, hospitals, companies, and civic initiatives. This dependence should not be seen as weakness. It reflects the real structure of modern crisis response. No single institution can manage a pandemic alone. The historical question is whether institutions know how to collaborate quickly without losing their specific functions. The Academy's experience during COVID-19 suggests that its greatest value lay in flexible mobilisation of specialised knowledge. It could supply capacity and expertise, but it could not substitute for governance. This distinction is important because it prevents unrealistic expectations and clarifies the proper place of public research institutions in emergencies (*Academy of Sciences of the Czech Republic, 2020*; *OECD, 2023*).

Public health crises also force science to confront time. Academic research usually works through long cycles: grant proposals, experiments, publications, peer review, doctoral training, and infrastructure development. A crisis demands speed. Samples must be tested today, models updated tomorrow, public explanations given immediately, and materials evaluated before shortage becomes catastrophe. The Academy's response showed that rapid action is possible only when slow preparation has already occurred. Laboratories could move quickly because trained people, equipment, methods, and institutional trust already existed. This temporal paradox is one of the most important lessons of the pandemic. Emergency science is built during non-emergency years. The post-1993 investments in molecular biology, diagnostics, biotechnology, modelling, materials science, and social research were not designed only for COVID-19, but they created the capacity to respond to it. This gives the pandemic a retrospective meaning in the Academy's institutional history. It confirmed the value of long-term public research in a way that ordinary policy documents could not (*Academy of Sciences of the Czech Republic, 2020*; *Šúri et al., 2025*).

The Academy's pandemic response also belongs to the history of interdisciplinarity. COVID-19 was a single disease caused by a virus, but the crisis it produced crossed almost every disciplinary boundary. Molecular diagnostics required biology and chemistry. Aerosol protection required physics, chemical engineering, and materials science. Viral evolution required genomics, bioinformatics, and evolutionary theory. Epidemiological scenarios required mathematics and computer science. Vaccination behaviour required economics, psychology, sociology, and communication studies. Ethical questions required philosophy, law, and social theory. Economic recovery required macroeconomic and labour-market analysis. This complexity gave practical meaning to a feature often stated abstractly in Academy self-descriptions: the coexistence of natural, technical, social, and human sciences. During COVID-19, that coexistence was not ornamental. It allowed the Academy to respond to different dimensions of the same crisis. This is an important institutional lesson because future public-health threats will also be multidimensional. Antimicrobial resistance, climate-related disease shifts, zoonotic spillovers, air pollution, mental-health crises, and ageing-related vulnerability will require similarly broad scientific capacity (*Academy of Sciences of the Czech Republic, 2020*; *World Health Organization Regional Office for Europe, 2023*).

The crisis also intensified the relationship between national resilience and European integration. The Czech Republic needed domestic testing capacity, laboratories, experts, and public communication. At the same time, it depended on international information about the virus, variants, diagnostics, vaccines, therapeutic trials, and public-health practice. Academy institutes operated at this intersection. They served Czech society, but they used and contributed to global science. This dual position captures one of the central themes of the Academy's post-1993 development. National autonomy in science does not mean self-sufficiency. It means having enough domestic competence to participate intelligently in international networks and to apply global knowledge under local conditions. During COVID-19, countries without strong domestic scientific institutions were more dependent on external interpretation and slower to adapt. The Academy's contribution therefore formed part of Czech scientific sovereignty in a Europeanised world. It helped the state not by isolating it from international science, but by making it capable of using international science effectively (*European Medicines Agency, 2023*; *Czech Academy of Sciences, n.d.*).

The pandemic also changed the public perception of basic research. Before COVID-19, molecular biology, genomics, aerosol measurement, or behavioural economics could appear remote from everyday life. During the pandemic, citizens heard about PCR, RNA, variants, aerosols, antibodies, vaccine efficacy, modelling, and statistical uncertainty in daily news. This sudden public visibility was not always comfortable for scientists. Concepts were simplified, politicised, or misunderstood. Yet the crisis opened a space in which the Academy could show why basic knowledge matters. A country cannot invent molecular diagnostics without molecular biology. It cannot interpret variants without genomics. It cannot evaluate masks without aerosol science. It cannot improve vaccination uptake without behavioural evidence. It cannot manage school closures without social research. The Academy's pandemic role therefore strengthened the public argument for maintaining a broad research base even when no emergency is visible. This argument was not theoretical. It was demonstrated in practice, under pressure, in front of society (*Academy of Sciences of the Czech Republic, 2020*; *Bartoš et al., 2022*).

At the same time, COVID-19 revealed the dangers of overpromising science. Public expectation during a crisis can be impatient and emotionally charged. People want definitive

answers, immediate treatments, reliable predictions, and clear rules. Science often proceeds more cautiously. Early findings may change, variants may alter assumptions, models may require revision, and interventions may have uncertain social consequences. Academy scientists therefore had to communicate uncertainty without appearing indecisive. This is one of the hardest tasks of crisis science. If experts sound too confident, they may lose trust when evidence changes. If they sound too cautious, policymakers and citizens may interpret caution as ignorance. The Academy's role was to hold this difficult middle position. Its authority depended not on infallibility but on disciplined openness to evidence. In this sense, the pandemic pushed the Academy further into a modern democratic mode of expertise, where credibility comes from transparency, correction, and methodological seriousness rather than from institutional prestige alone (*OECD, 2023*; *Academy of Sciences of the Czech Republic, 2022*).

The end of the international PHEIC in May 2023 did not end the historical importance of the Academy's pandemic experience. It shifted the problem from emergency response to preparedness, memory, and institutional learning. What should remain from the crisis? Laboratories that can scale testing. Genomic surveillance capacity. Better connections between research institutes and public-health authorities. Stronger data systems. More mature science communication. Recognition of behavioural science. Clearer ethical frameworks. Better integration between national and European response systems. The Academy's experience can be understood as a rehearsal for future crises. Those crises may involve respiratory viruses, antimicrobial resistance, zoonotic diseases, climate-related health risks, environmental exposures, food safety, or mental-health consequences of social disruption. The specific pathogen or threat may differ, but the institutional lesson is similar. A society needs research organisations that are broad enough to understand complexity, stable enough to preserve expertise, and flexible enough to mobilise quickly. The Academy's pandemic response therefore belongs to the future as much as to the past (*World Health Organization Regional Office for Europe, 2023*; *Šúri et al., 2025*).

The crisis also added a new layer to the Academy's relationship with the Czech state. Since 1993, CAS had repeatedly negotiated its autonomy, funding, evaluation, and public role. During the pandemic, autonomy did not mean distance from the state. It meant the ability to provide expertise that was not merely political instruction. The Academy could support state needs precisely because it was not a ministry. Its scientists could test, analyse, model, explain, and advise from the position of professional research institutions. This relationship was delicate. Science could inform policy, but policy had to make decisions involving values, risks, economics, law, and political responsibility. The pandemic showed that the Academy's public function is strongest when its autonomy and usefulness reinforce one another. If science is too subordinate to government, it loses credibility. If it is too detached from public need, it loses relevance. The post-1993 Academy had been built around this balance, and COVID-19 tested it under extreme conditions (*Czech Academy of Sciences, n.d.*; *Academy of Sciences of the Czech Republic, 2020*).

The Academy's experience during public-health crisis also revealed the importance of leadership and coordination. CAS President Eva Zažímalová publicly framed the Academy as being "on the same ship" with society, while Jan Konvalinka from IOCB helped coordinate academic coronavirus research. Such statements and roles mattered because scientific response in a crisis requires more than dispersed goodwill. It requires coordination, public messaging, institutional trust, and the ability to connect laboratories with authorities and

users. Leadership in this context did not mean command in the old centralised sense. It meant creating channels through which expertise could become effective. The Academy's post-socialist governance structure, with institutes retaining autonomy but belonging to a common institutional framework, was tested by this need for coordination. The crisis showed that decentralised institutes can act collectively when the institution has enough shared identity and public purpose. This is an important finding for the broader history of the Academy's modernisation. Autonomy need not fragment an academy if it is balanced by common responsibility (*Academy of Sciences of the Czech Republic, 2020*).

COVID-19 also connected the Academy with civic and popular initiatives. Early in the pandemic, Czech society saw volunteer networks, technical communities, universities, companies, and research institutions working together on protective equipment, data tools, and emergency support. The Academy's contribution took place within this wider civic mobilisation. This context matters because it shows that scientific institutions are not isolated towers of expertise. During crises, they become part of a social ecosystem of response. Their credibility and usefulness depend on how well they cooperate with hospitals, schools, public authorities, firms, media, and citizens. The pandemic therefore pushed the Academy further into a public-facing role that had already grown after 1989. Yet it also reminded society that spontaneous civic energy needs expert validation. Protective materials, diagnostics, devices, and epidemiological claims must be tested and interpreted. The Academy's role was often to provide that validation, turning goodwill into safer and more reliable action (*Academy of Sciences of the Czech Republic, 2020*; *Tietze, Vimalnath, Aristodemou, & Molloy, 2020*).

The public-health crisis also had an archival and historical dimension. The Academy's pandemic activities created documents, datasets, media statements, scientific publications, policy analyses, institutional memories, and personal experiences that future historians will use to study Czech science in the early 21st century. This matters for the present project because the pandemic should not be treated merely as recent news. It is already part of the institutional history of CAS. It revealed capacities, weaknesses, networks, leadership styles, disciplinary interactions, public expectations, and the meaning of science in democratic society. In earlier chapters of this history, the Academy's relationship with political regimes, national culture, and scientific autonomy was central. COVID-19 added a new configuration: the relationship between the Academy, public health, emergency governance, and societal resilience. This configuration does not replace the older themes. It extends them. The question is still how science relates to the state and society, but the crisis made the question urgent, bodily, and visible to every citizen.

Thus, the Academy during public health crises demonstrated that the post-1993 transformation of Czech science had created more than a set of reformed institutes. It had created a reservoir of national resilience. During COVID-19, the Academy contributed through molecular testing, diagnostic development, genomic surveillance, antiviral and chemical expertise, materials analysis, modelling, behavioural research, economic analysis, ethical reflection, public communication, and educational outreach. These activities were possible because earlier decades had built laboratories, infrastructures, research groups, technology-transfer mechanisms, university partnerships, and international networks. The pandemic therefore confirmed one of the deepest principles of the Academy's modern history: scientific autonomy is socially valuable when it preserves capacities that cannot be improvised during emergencies. CAS did not become a public-health authority, but it became an indispensable part of the public-health knowledge system. Its experience showed that basic research, when

institutionally stable and publicly accountable, can become crisis science without ceasing to be science. In this sense, COVID-19 was not only a medical and social emergency; it was also a test of the Academy's post-socialist identity, and the Academy's response showed the practical meaning of continuity, renewal, interdisciplinarity, and public responsibility.

Biotechnology, Bioinnovation, and Applied Research

1. From Laboratory Discoveries to Practical Applications

After 1993, the relationship between laboratory discovery and practical application became one of the most important tests of the Academy of Sciences of the Czech Republic as a modern public research institution. The question was not whether the Academy should abandon basic research in favour of immediate economic use, because such a move would have weakened precisely the scientific foundations from which important applications arise. The real question was how a post-socialist academy, historically shaped by strong disciplinary institutes and long-term research programmes, could create pathways through which selected discoveries might travel towards medicine, biotechnology, diagnostics, agriculture, environmental technologies, materials, or industry. This was a difficult transition because the old Czechoslovak Academy had possessed applied institutes and state-directed research tasks, but it had not operated within a market economy, a competitive intellectual-property environment, or a European innovation ecosystem. After 1993, practical application increasingly required patents, licensing, industrial partners, venture capital, technology-transfer offices, regulatory awareness, quality standards, and international business competence. These were not natural extensions of traditional academic culture. They had to be learned, institutionalised, and reconciled with the autonomy of science. In the life sciences, this reconciliation was especially delicate because practical benefit could be socially profound, particularly in medicine and environmental protection, but premature application could also distort research priorities. The Academy's life-science institutes therefore developed a model in which basic discovery remained the source of value, while technology transfer, infrastructures, and partnerships created possible routes towards use. This model did not promise that every discovery would become a product. It recognised that application is selective, uncertain, and often long-term (*Czech Academy of Sciences, n.d.*; *IOCB Prague, n.d.*).

The post-1993 transformation changed the meaning of applied research itself. Under state socialism, "application" had often been connected with planned production, ministerial priorities, agriculture, industry, military needs, or health-sector assignments. In the democratic and market-oriented Czech Republic, application came to mean something more plural and less centrally directed. It could involve a licensed compound developed by a multinational pharmaceutical company, a diagnostic method validated with hospitals, a biomaterial tested for regenerative medicine, a plant biotechnology tool used in agriculture, a microbial product with industrial potential, a research infrastructure serving external users, or a spin-off company carrying academic knowledge into a commercial environment. This

plurality required a new institutional imagination. The Academy could no longer assume that practical use would be organised by the state alone. Nor could it simply hand discoveries to industry without professional mediation. Life-science applications require careful protection of intellectual property, experimental validation, reproducibility, financing, clinical or regulatory development, and market assessment. These requirements changed the internal culture of research institutes. Scientists had to become more aware of patents, licensing, confidentiality, invention disclosure, and collaboration agreements. At the same time, institutes had to protect the freedom of researchers to pursue questions that might have no immediate application. The Academy's post-1993 applied life sciences therefore emerged from a tension between openness and protection, curiosity and usefulness, publication and patenting, public mission and commercial partnership (*IOCB Prague, n.d.*; *IOCB Tech, n.d.*).

The most powerful example of this long movement from discovery to application remains the antiviral research associated with Antonín Holý and the Institute of Organic Chemistry and Biochemistry. Although the origins of this work predate 1993, its consequences shaped the post-socialist Academy's understanding of applied potential. Holý's research on acyclic nucleoside phosphonates was not born as a short-term commercial project. It grew out of sustained synthetic chemistry, biochemical imagination, international collaboration, and the willingness to pursue unusual molecular structures over many years. The eventual development of antiviral medicines against HIV/AIDS, hepatitis B, and other viral diseases required cooperation with Erik De Clercq, Gilead Sciences, clinical developers, regulators, and pharmaceutical markets. This case therefore shows that practical application is rarely a direct line from laboratory bench to patient. It is a chain of scientific, institutional, legal, industrial, and medical transformations. The Academy's role was crucial at the beginning of the chain, where basic chemical and biological insight produced compounds with extraordinary potential. The post-1993 significance of the case lay in its demonstration that a Czech Academy institute could generate discoveries of global medical importance. It also gave the Academy a persuasive argument in debates about research funding: the social and economic value of basic research may become visible only after long and unpredictable development (*IOCB Prague, n.d.*; *Gilead Sciences, 2006*; *Gilead Sciences, 2011*).

The Gilead–IOCB partnership became a model of how application could be sustained through long-term international cooperation. The establishment of the Gilead Sciences Research Centre at IOCB Prague in 2006, with annual support for selected research groups, symbolised a new stage in the relationship between Czech public research and global pharmaceutical development. It was not simply a reward for past discoveries. It created a structure through which medicinal chemistry and human-disease research could continue in Prague with international industrial support. The partnership also helped normalise the idea that public institutes could cooperate with major companies without ceasing to be academic institutions. This was important in a post-socialist context where commercialisation could be viewed either with excessive suspicion or with unrealistic enthusiasm. The IOCB experience suggested a more mature position. Industry partnership can be valuable when it is based on strong science, clear agreements, intellectual-property competence, and respect for academic quality. It can also return resources to the research environment, supporting further discovery. The case did not mean that all Academy institutes should follow the same path, because fields differ greatly in their translational possibilities. Yet it gave the Academy a visible example of application grounded in excellence rather than administrative pressure (*Gilead Sciences, 2006*; *IOCB Prague, n.d.*).

The institutionalisation of technology transfer at IOCB marked another important step. In the early post-socialist period, many research institutions across Central and Eastern Europe possessed scientific talent but lacked mature mechanisms for commercialisation. Researchers might publish results, but potential inventions could remain unprotected, underdeveloped, or poorly connected to industrial partners. IOCB Tech was created to address precisely this problem. Its responsibilities included identifying commercially promising projects, analysing market potential and patentability, protecting intellectual property, supporting project development, finding commercial partners, and negotiating licensing agreements. Such functions may appear administrative, but historically they represent a major cultural transformation. They translate academic discovery into a language that investors, companies, patent offices, and development partners can understand. They also protect scientists from having to navigate complex commercial processes alone. The existence of a professional transfer structure means that application is no longer an accidental by-product of personal contacts. It becomes an organised institutional capacity. In the Academy's life sciences, this capacity was essential because biomedical and biotechnological applications often require many years, large investments, and specialised legal knowledge (*IOCB Tech, n.d.*; *EATRIS, n.d.*).

The creation of i&i Prague in 2017 extended this logic from technology transfer towards venture building and spin-off support. Founded by IOCB Prague, i&i Prague was designed to support the commercialisation of Czech research results, help academic institutions and universities identify and protect inventions with commercial potential, and find commercial partners. It also provided pre-seed financing and commercial expertise for innovative projects, including those outside IOCB itself. This was historically significant because it moved the Academy-linked innovation model beyond the walls of one institute. IOCB's success became a platform for a wider Czech academic ecosystem. The life sciences are particularly dependent on early-stage support because many discoveries are too risky for established companies and too immature for conventional investment. Spin-offs, incubators, and specialised funds help bridge this gap. They do not guarantee success, but they create a space where academic results can be developed beyond publication. The establishment of i&i Prague therefore represented a shift from isolated technology transfer to ecosystem building. It showed that the Academy could participate in the creation of institutional intermediaries between research and market without transforming itself into a commercial enterprise (*IOCB Prague, 2017*; *i&i Prague, n.d.*).

The i&i Biotech Fund, established in 2021 in cooperation with the European Investment Fund, further demonstrated the maturation of this ecosystem. Its focus on innovative European life-science companies in drug discovery, medical devices, diagnostics, and digital health placed Czech academic innovation within a broader European investment environment. This matters because the life sciences are expensive, risky, and internationally competitive. A promising diagnostic tool, compound, or medical device often cannot advance without venture financing, development expertise, and access to international partners. The creation of a dedicated fund signalled that Czech academic life sciences had moved beyond the stage of occasional licensing. They were beginning to generate projects that required structured investment pathways. For the Academy's institutional history, this development is important because it shows how applied research became part of a wider financial and entrepreneurial infrastructure. The Academy itself remained a public research organisation, but its discoveries could enter a network of technology-transfer subsidiaries, incubators, venture funds, and

international investors. This networked model reflects the reality of contemporary bioinnovation, where scientific value must pass through several institutional environments before it reaches society (*i&i Prague, n.d.*; *CzechInvest, 2021*).

The opening of IOCB Boston in 2024 added a global dimension to this applied trajectory. Located in one of the world's leading biotechnology hubs, IOCB Boston was intended to showcase Czech projects and provide transfer support, including the search for American investors. This step is historically striking because it represents almost the inverse of the restricted international position of Czech science before 1989. A Czech Academy institute was no longer only trying to gain access to Western laboratories; it was creating an outpost in a global centre of biotechnology. The aim was not simply prestige. It was to connect Czech scientific projects with the dense ecosystem of investors, companies, legal expertise, experienced entrepreneurs, and biomedical developers that characterises Boston. This move shows that practical application in the 21st-century life sciences is increasingly international from the beginning. A Czech discovery may be made in Prague, but its development may require partners in the United States, Europe, or elsewhere. The Academy's applied life sciences therefore became geographically extended. They remained rooted in Czech public research, but their routes to use could pass through global innovation hubs (*IOCB Prague, 2024*).

The Institute of Biotechnology of the Czech Academy of Sciences represented a different but complementary path from discovery to application. Established in 2008, it was formed in a period when biotechnology, molecular medicine, and translational expectations were already central to European research policy. Its mission was grounded in excellent basic research in biomedical molecular biology, but with prospective transfer of biotechnological methods and tools to human and veterinary medicine or other important areas of human activity. This formulation captures the Academy's preferred balance. The institute was not created as a commercial development company, yet application was part of its horizon from the beginning. Its work on biomolecular mechanisms, protein engineering, structural biology, disease-related processes, and biomedical tools showed how the boundary between fundamental and applied research had become more permeable. The Institute of Biotechnology did not merely inherit a Czechoslovak disciplinary tradition; it embodied a new institutional generation shaped by European infrastructure, university cooperation, and translational potential. Its establishment showed that the post-1993 Academy was not limited to reforming old institutes. It could create new institutes aligned with emerging scientific and societal needs (*Institute of Biotechnology of the Czech Academy of Sciences, n.d.*; *EMBL ARISE, n.d.*).

BIOCEV became the spatial and organisational environment in which much of this new biotechnology could mature. As a biotechnology and biomedicine centre of the Academy and Charles University, BIOCEV focused research and development on selected areas of biotechnology and biomedicine and organised its scientific scope through mutually integrated research programmes. This mattered because applied life-science research rarely arises from isolated laboratories. It depends on critical mass, advanced equipment, doctoral training, shared services, and interaction among molecular biologists, physicians, chemists, structural biologists, microbiologists, geneticists, and technologists. BIOCEV was built on precisely this logic. It created a campus environment where fundamental mechanisms could be studied with possible diagnostic, therapeutic, and biotechnological outcomes in mind. It also addressed a structural problem inherited from the socialist period: the separation between Academy research and university teaching. By bringing Academy institutes and Charles University

together, BIOCEV allowed application-oriented research to interact with education and clinical knowledge. This made it one of the most important post-1993 platforms for moving life-science discoveries towards practical use (*BIOCEV, n.d.*; *Institute of Microbiology of the Czech Academy of Sciences, n.d.*).

Research infrastructures were essential to this movement from laboratory discovery to application. In the life sciences, a discovery often cannot move towards use unless it can be reproduced, scaled, visualised, modelled, screened, or validated. Czech-BioImaging, CZ-OPENSCREEN, the Czech Centre for Phenogenomics, ELIXIR CZ, and EATRIS-CZ all contributed to this capacity. Czech-BioImaging made advanced biological and medical imaging available across institutions. CZ-OPENSCREEN supported chemical biology, screening, molecular probes, and early therapeutic exploration. The Czech Centre for Phenogenomics enabled genetic engineering and standardised phenotyping of animal models. ELIXIR CZ provided biological data and bioinformatics infrastructure. EATRIS-CZ linked Czech biomedical, chemical, and clinical research to the European translational medicine environment. These infrastructures changed the meaning of applied research. Application was no longer imagined as a final step after discovery; it became dependent on platforms present throughout the research process. A compound needs screening, a disease hypothesis needs models, a cellular mechanism needs imaging, a biomarker needs data, and a therapeutic idea needs translational validation. The Academy's applied potential therefore rested increasingly on infrastructural depth (*Czech-BioImaging, n.d.*; *CZ-OPENSCREEN, n.d.*; *Czech Centre for Phenogenomics, n.d.*; *EATRIS-CZ, n.d.*).

CZ-OPENSCREEN illustrates especially well the early phase of practical translation. Chemical biology is concerned with small molecules that can probe, modulate, or reveal biological processes. Such molecules may become research tools, diagnostic aids, target validators, or early therapeutic candidates. The infrastructure hosted at the Institute of Molecular Genetics created open access to compound libraries, screening technologies, assay expertise, and chemical-biology services. This made it possible for academic laboratories to move from a biological hypothesis towards molecular intervention. The importance of such a platform lies in its position before conventional drug development. It operates where scientific uncertainty is still high, but where practical potential may begin to appear. By supporting molecular probes and screening, CZ-OPENSCREEN helped convert basic biological mechanisms into experimentally manipulable systems. In institutional terms, this strengthened the Academy's capacity to participate in bioinnovation without becoming dependent on pharmaceutical companies at the earliest stage. It allowed researchers to generate more mature and credible findings before seeking external development partners (*CZ-OPENSCREEN, n.d.*).

The Czech Centre for Phenogenomics similarly supported the transition from gene-level discovery to functional and preclinical knowledge. Many modern biomedical discoveries begin with a gene, variant, pathway, or cellular observation, but practical application requires evidence of function in a living organism. Phenogenomics provides precisely this bridge. Through genetically modified mice and rats, standardised phenotyping, imaging, pathology, behavioural analysis, metabolism, and data systems, researchers can test how molecular changes affect whole organisms and disease models. This is essential for translational research because therapies cannot be judged only in cell cultures. They must be understood in systemic biological contexts. The centre's location at BIOCEV and its connection with the Institute of Molecular Genetics gave the Academy a strong position in model-organism-based biomedical research. It also linked Czech science to European infrastructures for mouse

functional genomics. In the applied life sciences, this kind of platform reduces the distance between discovery and validation. It does not guarantee clinical success, but it makes research more credible, reproducible, and development-ready (*Czech Centre for Phenogenomics, n.d.*; *INFRAFRONTIER, n.d.*).

Biomaterials research opened another pathway from laboratory discovery to practical application. The Institute of Macromolecular Chemistry had a long tradition in polymer science, and after 1993 this tradition increasingly intersected with biomedical needs. Drug delivery systems, hydrogels, tissue scaffolds, wound-healing materials, bioresponsive polymers, and materials for regenerative medicine require exactly the kind of macromolecular expertise that a chemistry-oriented Academy institute can provide. The path to application here differs from the path of a drug molecule. A biomaterial must be biocompatible, mechanically suitable, degradable or stable as required, manufacturable, sterilizable, and acceptable under medical regulation. It must interact with cells and tissues in controlled ways. This makes biomaterials research deeply interdisciplinary. It requires polymer chemistry, cell biology, physiology, medicine, engineering, and often industrial development. The Academy's strength was its ability to sustain advanced materials research while connecting it to biological and medical questions. In this way, polymer laboratories contributed to the applied life sciences even when they stood outside the formal biological-medical section (*Institute of Macromolecular Chemistry of the CAS, n.d.*).

Microbiology and microbial biotechnology formed another important field of application. Microorganisms are sources of enzymes, metabolites, antibiotics, immunomodulators, industrial processes, environmental technologies, and diagnostic tools. The Institute of Microbiology's research on microbial physiology, molecular microbiology, immunology, biotechnology, natural products, environmental microbiology, and host-microbe interactions created multiple routes towards use. Some applications may relate to medicine, such as antimicrobials, immunological tools, or microbiome-related insights. Others may relate to industry, agriculture, waste processing, soil systems, water quality, or bioactive compounds. Microbial biotechnology is historically significant because it connects older applied traditions with modern molecular methods. Under socialism, microbiology already had practical significance for industry and agriculture. After 1993, its application potential became reframed through patents, international cooperation, European projects, and biotechnology platforms. The field therefore shows continuity and renewal at the same time. It preserved practical relevance while entering a more open and competitive innovation system (*Institute of Microbiology of the Czech Academy of Sciences, n.d.*).

Plant biotechnology and experimental botany also contributed to practical application, although their routes differed from biomedical translation. The Institute of Experimental Botany worked on plant genetics, physiology, biotechnology, structural and functional genomics, DNA repair, pollen biology, plant development, hormones, plant viruses, stress responses, and plant pathophysiology. Such research can support agriculture, breeding, plant health, food security, environmental resilience, and adaptation to climate change. Its applied potential may appear in new diagnostic tools for plant pathogens, improved understanding of stress tolerance, biotechnological methods, or strategies for sustainable cultivation. In the post-1993 period, plant biotechnology became increasingly important because agriculture faced both economic and environmental pressures. Climate change, drought, disease, soil degradation, and the need for sustainable production made plant research socially relevant in new ways. The Academy's contribution was not to replace agricultural companies or breeding stations,

but to generate knowledge of plant mechanisms that could later inform practical solutions. This again demonstrates the Academy's preferred model: fundamental research with a horizon of public usefulness (*Institute of Experimental Botany of the Czech Academy of Sciences, n.d.*).

Environmental biotechnology and ecological applications broadened the field further. Life-science application was not confined to medicine and agriculture. It also included water quality, soil processes, biodiversity monitoring, invasive species management, bioremediation, algal technologies, and ecosystem restoration. Institutes such as the Biology Centre CAS, the Institute of Botany, and the Institute of Microbiology contributed to this broader applied landscape. Ecological knowledge may become practical when it informs conservation plans, restoration strategies, pest management, water treatment, or environmental risk assessment. Such applications are often less commercially visible than drugs or medical devices, but they are crucial for society. They also challenge narrow definitions of innovation. A better method for monitoring biodiversity, managing invasive species, assessing soil health, or protecting freshwater ecosystems may not produce a spin-off company, yet it may have substantial public value. The Academy's life sciences therefore participated in both market-oriented and public-good innovation. This distinction is essential for evaluating applied research fairly (*Biology Centre CAS, n.d.*; *Institute of Botany of the Czech Academy of Sciences, n.d.*).

Strategy AV21 gave this broader public-good orientation an institutional language. Its formula of "top research in the public interest" expressed the idea that Academy research should respond to contemporary problems through coordinated, interdisciplinary programmes while preserving excellence. This was important for the applied life sciences because not all practical applications fit the commercialisation model. Public health, ageing, biodiversity loss, environmental change, food security, and diagnostic methods may require scientific solutions whose value is social, regulatory, or infrastructural rather than immediately profitable. Strategy AV21 therefore complemented technology-transfer mechanisms. IOCB Tech and i&i Prague supported commercial pathways; Strategy AV21 framed research around societal challenges and public interest. Together, these instruments show that applied research in the Academy after 1993 had more than one route. Some discoveries moved towards patents and firms; others moved towards expert advice, infrastructures, methods, standards, or public policy. The Academy's applied mission was strongest when it recognised this plurality rather than forcing all research into one innovation template (*Strategy AV21, n.d.*; *Institute of Psychology of the CAS, n.d.*).

The development of diagnostic methods and techniques became one of the practical areas where public-interest research and innovation overlapped. Diagnostic innovation may produce commercial products, but it may also strengthen public health, hospital practice, environmental monitoring, or research capacity. The Academy's biological and technical institutes contributed to diagnostics through molecular biology, imaging, nanotechnology, bioinformatics, chemical probes, animal models, and materials. The COVID-19 pandemic later made the public value of diagnostic capacity dramatically visible, but the foundations had been built earlier. Diagnostic application requires reliable detection, sensitivity, specificity, reproducibility, and integration into clinical or monitoring systems. These qualities depend on deep science and careful validation. In the Academy's context, diagnostic development was therefore a natural field for cooperation among basic researchers, clinicians, engineers, and transfer specialists. It also showed that applied research is often methodological. A new method can change what other scientists, doctors, or public agencies are able to see and

measure. Such methodological innovation may be as important as a single product (*Strategy AV21, n.d.*; *EATRIS-CZ, n.d.*).

The movement from laboratory discovery to application also depended on changing attitudes among scientists themselves. In older academic cultures, commercialisation could be seen as secondary, suspicious, or inappropriate for serious research. After 1993, especially in biomedical and biotechnological fields, this attitude gradually changed. Researchers became more aware that patents do not necessarily contradict publication, that spin-offs can preserve scientific value if well governed, and that industry collaboration can support further research. Yet the change was uneven. Not every scientist wanted to become an entrepreneur, and not every discovery deserved commercial development. The Academy therefore needed intermediaries who could recognise potential without imposing business logic on all laboratories. This is why technology-transfer offices, incubators, and project managers became important. They allowed scientists to remain scientists while making application possible where appropriate. The cultural transformation of applied research was therefore not a conversion of academic people into business people. It was the creation of institutional roles that made communication between science and business more competent (*IOCB Tech, n.d.*; *i&i Prague, n.d.*).

Intellectual property became central to this transformation. In the life sciences, a discovery may lose practical value if it is disclosed without protection before development partners are identified. At the same time, excessive secrecy can undermine scientific openness and slow collective progress. Post-1993 Academy institutes had to learn to balance these concerns. Patentability, market potential, licensing, invention disclosure, and confidentiality agreements entered the world of laboratories that had once been organised primarily around publications and institutional reports. This was a major institutional and psychological change. It required training, legal advice, trust between scientists and technology-transfer professionals, and clear rules about benefit sharing. It also required understanding that not all valuable research is patentable. Some knowledge is valuable because it informs policy, improves methods, supports public health, or enriches basic understanding. The strongest technology-transfer culture is therefore selective and intelligent. It protects what should be protected while preserving openness where openness best serves science and society (*IOCB Prague, n.d.*; *IOCB Tech, n.d.*).

Application also required validation, and validation often proved more difficult than discovery itself. A promising molecule may work in vitro but fail in animals. A biomarker may appear useful in a small dataset but not in a diverse population. A material may perform well in laboratory conditions but encounter safety, manufacturing, or regulatory obstacles. A plant-biotechnology result may be biologically sound but agronomically impractical. A microbial product may be effective but economically difficult to produce. The Academy's applied research therefore needed infrastructures and partnerships that could test discoveries under more demanding conditions. Phenogenomics, imaging, screening, translational medicine networks, university hospitals, and industrial collaborations all helped address this problem. Historically, this is where the post-socialist Academy had to move beyond the old belief that a good scientific result naturally becomes useful. Practical application requires systems of proof. The Academy's modernisation involved building parts of those systems while recognising that many projects would still not reach the final stage of use (*Czech Centre for Phenogenomics, n.d.*; *EATRIS, n.d.*).

The European context strongly shaped this development. European research policy after the 1990s increasingly emphasised competitiveness, knowledge transfer, biotechnology, health innovation, sustainability, and the connection between research and society. More recently, the European Commission's life-sciences strategy has framed life sciences as a field central to Europe's future competitiveness and resilience. Czech Academy institutes operated within this wider policy environment. European programmes encouraged collaboration, infrastructure development, applied potential, and links between public research and users. This helped the Academy modernise its applied pathways, but it also created pressure to speak the language of impact. The challenge was to avoid reducing impact to short-term commercial metrics. In the life sciences, true impact may take decades and may appear in unexpected places. The Academy's experience shows that European innovation policy is most productive when it supports both application and the basic research from which application grows. If the second is weakened, the first becomes shallow (*European Commission, 2025*; *Strategy AV21, n.d.*).

The Czech national context also mattered. The Czech Republic is a medium-sized research system with strong scientific traditions but limited domestic pharmaceutical and biotechnology scale compared with the United States, Germany, Switzerland, or the United Kingdom. This meant that Academy discoveries often needed international partners to reach full application. The IOCB–Gilead story is a clear example. It also meant that domestic technology-transfer structures had to help Czech projects become visible beyond national borders. IOCB Boston, i&i Prague, i&i Biotech Fund, and international infrastructure participation all responded to this structural condition. Czech bioinnovation could not rely only on the domestic market. It had to connect early with European and global development systems. For the Academy, this created a dual responsibility: to serve Czech society and to position Czech discoveries internationally. The route from laboratory to application therefore often passed through transnational networks, even when the original discovery was made in a Czech public institute (*IOCB Prague, 2024*; *i&i Prague, n.d.*).

The Academy's applied life sciences were also shaped by cooperation with universities and hospitals. Laboratory discoveries become medically or biologically useful only when they interact with educational systems, clinical knowledge, patient-related expertise, field sites, and validation environments. BIOCEV, EATRIS-CZ, Czech-BioImaging, and many doctoral collaborations reflected this reality. The Academy's institutes brought long-term research capacity and specialised infrastructures; universities brought students, faculties, and often medical or teaching environments; hospitals brought clinical questions, samples, patient cohorts, and practical knowledge of disease. Application emerged where these capacities met. This was particularly important because the Academy's post-1993 institutional identity remained non-university and non-clinical. Its practical contribution therefore depended on partnerships rather than institutional self-sufficiency. The movement from laboratory discovery to application was, in this sense, a movement from institutional separation to functional cooperation (*BIOCEV, n.d.*; *EATRIS-CZ, n.d.*).

Not all applications were successful, and this must be acknowledged in a serious institutional history. Bioinnovation is inherently uncertain. Many promising projects fail because biology is complex, markets are limited, regulation is demanding, funding is insufficient, or evidence does not survive validation. The existence of technology-transfer structures does not eliminate this uncertainty. It manages it. A mature Academy does not measure applied success only by a few spectacular cases, but by the creation of an environment in which good ideas can be

recognised, tested, protected, and developed when appropriate. Failures are part of such an environment. They can still produce knowledge, methods, trained people, and improved judgement. This point is important because public discussion often expects a direct return on investment from research. The history of life-science application shows a more complicated economy of value. The Academy's strongest applied contribution may lie in maintaining a pipeline of possibilities, only some of which become practical technologies (*IOCB Tech, n.d.*; *EATRIS, n.d.*).

The movement from discovery to application also changed the Academy's public narrative. In earlier periods, the Academy's legitimacy had often been defended through national culture, scientific prestige, or autonomy from political interference. After 1993, especially in the life sciences, the Academy increasingly had to explain how its research could improve health, sustainability, technology, and economic development. This did not replace the older narrative, but it added a new layer. The Academy could point to antiviral drugs, diagnostic tools, biomaterials, biotechnology platforms, plant science, environmental expertise, and research infrastructures as evidence of social usefulness. Yet the most responsible version of this narrative avoided exaggeration. It did not claim that every laboratory would produce a product. It argued that a society needs deep scientific institutions because practical breakthroughs arise unpredictably from them. In this sense, applied research became part of the Academy's democratic communication with society. It helped citizens see why public investment in advanced science matters (*Czech Academy of Sciences, n.d.*; *IOCB Prague, n.d.*).

The life sciences were particularly well suited to this narrative because their applications touch ordinary life. Antiviral drugs affect patients with serious infections. Diagnostic methods affect early detection. Biomaterials affect repair and regeneration. Plant biotechnology affects food and agriculture. Microbial biotechnology affects health, industry, and environment. Biodiversity research affects conservation and ecosystem resilience. These applications are not abstract. They enter bodies, hospitals, fields, water systems, companies, and public policy. The Academy's life sciences therefore made the social relevance of research unusually visible. At the same time, they also revealed the ethical complexity of application. Medical technologies, animal models, genetic tools, environmental interventions, and commercial partnerships all require responsible governance. Practical application is not automatically good merely because it is practical. The Academy had to cultivate an applied research culture guided by scientific quality, public interest, ethical standards, and long-term responsibility (*EATRIS, n.d.*; *Strategy AV21, n.d.*).

By the 2020s, the Academy's route from laboratory discovery to practical application had become a multi-level system. At one level stood the institutes, where discoveries were generated through basic research. At another level stood infrastructures that made discoveries reproducible, measurable, and technically mature. At a third level stood technology-transfer offices, incubators, and funds that assessed patentability, market potential, licensing, and company creation. At a 4th level stood universities, hospitals, industry, investors, public agencies, and international partners. At a 5th level stood European and global policy frameworks shaping innovation, health, biotechnology, and sustainability. This layered structure was far more complex than the old image of applied science as a direct transfer from laboratory to factory. It was also more realistic. Life-science application requires ecosystems. The Academy's achievement after 1993 was not that it solved every problem of Czech bioinnovation, but that it helped build parts of such an ecosystem around strong public research (*i&i Prague, n.d.*; *BIOCEV, n.d.*; *European Commission, 2025*).

Thus, the movement from laboratory discoveries to practical applications after 1993 shows that the Academy of Sciences of the Czech Republic developed a distinctive model of applied life science. It did not abandon fundamental research, nor did it return to the centrally planned applied research of the socialist period. Instead, it gradually built pathways through which selected discoveries could move towards medicine, biotechnology, diagnostics, biomaterials, plant science, environmental solutions, and commercial development. The antiviral legacy of IOCB Prague, the Gilead partnership, IOCB Tech, i&i Prague, the i&i Biotech Fund, IOCB Boston, the Institute of Biotechnology, BIOCEV, CZ-OPENSCREEN, the Czech Centre for Phenogenomics, EATRIS-CZ, and research in microbiology, plant biotechnology, biomaterials, and environmental biology together demonstrate this transformation. The Academy's applied potential rested on continuity, but it required new institutions, new skills, and new partnerships. Its history shows that practical application is not the opposite of basic research. It is one possible future of basic research when scientific depth is joined with infrastructure, validation, intellectual-property competence, public responsibility, and international connectivity.

2. Cooperation with Universities, Hospitals, and Industry

After 1993, cooperation with universities, hospitals, and industry became one of the decisive conditions for the transformation of life-science research within the Academy of Sciences of the Czech Republic. The Academy had inherited from the Czechoslovak period a strong institute-based research model, in which many of the most advanced laboratories were located outside the university system. This model had significant advantages: it allowed concentration of expertise, long-term research programmes, specialised equipment, and professional research careers. Yet it also had structural limitations. Modern biotechnology, biomedicine, diagnostics, and translational research require not only strong institutes, but also doctoral training, clinical contact, patient-related expertise, regulatory knowledge, industry development, and routes towards application. No academy institute, however excellent, can alone cover the entire path from molecular discovery to medical use, industrial process, environmental technology, or commercial product. The post-1993 period therefore made cooperation not a polite institutional ideal, but a practical necessity. Universities provided education, students, faculties, and disciplinary breadth. Hospitals provided clinical questions, patient cohorts, biological samples, diagnostic needs, and therapeutic reality. Industry provided development capacity, manufacturing, regulatory experience, capital, and access to markets. The Academy's contribution lay in fundamental research, advanced infrastructures, scientific continuity, and methodological depth. Cooperation among these sectors became one of the central mechanisms through which Czech life sciences moved from inherited academic strength towards a modern innovation ecosystem (*Czech Academy of Sciences, n.d.; BIOCEV, n.d.*).

The relationship between the Academy and universities was especially important because it addressed one of the oldest structural divisions in Czechoslovak and Czech science. During the socialist period, the Academy of Sciences functioned as a major research sector, while universities were primarily responsible for teaching, although many university departments also conducted research. This division created strong academy institutes but could separate advanced research from student formation. After 1989 and 1993, such separation became increasingly problematic. Molecular biology, biotechnology, experimental medicine, ecology,

bioinformatics, and biomedicine all required young researchers trained in advanced laboratories. Universities needed access to infrastructures and research environments capable of supporting competitive doctoral work. Academy institutes needed students, postdoctoral researchers, and formal educational partnerships to reproduce expertise across generations. Cooperation therefore gradually became more organic. Academy scientists supervised doctoral students through university programmes, university students worked in Academy laboratories, and joint centres created shared spaces where education and research could intersect. This development changed the social structure of Czech science. It weakened the old boundary between the academy as a research estate and the university as a teaching estate. In the life sciences, this boundary could not survive unchanged because the laboratory itself became a training environment (*BIOCEV, n.d.; Institute of Molecular Genetics of the Czech Academy of Sciences, n.d.*).

BIOCEV became the clearest institutional expression of this new Academy-university cooperation. As the Biotechnology and Biomedicine Centre of the Academy of Sciences and Charles University, it brought together several Academy institutes and two faculties of Charles University in a shared research environment in Vestec. Its significance lay not merely in physical concentration or modern buildings. BIOCEV embodied a new model of Czech life-science organisation, one based on shared infrastructures, joint programmes, doctoral training, interdisciplinary platforms, and proximity between basic research and biomedical application. The centre's participating Academy institutes included major actors in molecular genetics, biotechnology, microbiology, physiology, experimental medicine, and macromolecular chemistry, while Charles University contributed educational, biomedical, and scientific capacities. This was a practical answer to the problem of fragmentation. Molecular life sciences require genomics, proteomics, imaging, model organisms, structural biology, cell biology, medicinal chemistry, and clinical awareness. No one institution can sustain all of these alone. BIOCEV therefore represented cooperation as infrastructure, not only cooperation as goodwill. It showed that post-1993 reform was not limited to statutes or funding mechanisms; it also required new spatial and organisational forms where institutions could work together without dissolving their identities (*BIOCEV, n.d.; Institute of Molecular Genetics of the Czech Academy of Sciences, 2015*).

The cooperation embodied in BIOCEV also had a symbolic meaning in the long history of the Academy. Earlier scientific institutions in the Czech lands often developed around learned societies, national cultural associations, museums, universities, and later state academies. After 1993, the challenge was no longer simply to create national scientific institutions, but to connect them efficiently. BIOCEV showed that the Academy could move beyond self-contained institute culture and enter a more networked mode of operation. This was especially important for biotechnology and biomedicine, where the path from discovery to use usually passes through several institutional contexts. A gene may be studied in an Academy laboratory, interpreted with university bioinformatics, validated in a model-organism facility, discussed with clinicians, protected through a technology-transfer office, and developed with an industrial partner. Such a path cannot be managed by one traditional department. It requires a collaborative environment in which different professional logics meet. BIOCEV gave Czech life science a place where these logics could be brought into regular contact. In this sense, it was not only a research centre, but a mechanism for overcoming inherited institutional separation (*BIOCEV, n.d.; EMBL ARISE, n.d.*).

Charles University was a particularly important partner because of its historical depth, medical faculties, and biological education. The cooperation between the Academy and Charles University linked two different forms of legitimacy. The Academy contributed specialised research institutes and long-term scientific programmes. Charles University contributed the prestige and infrastructure of one of Central Europe's oldest universities, together with students, medical faculties, and a broad disciplinary environment. In the life sciences, this complementarity was highly productive. University faculties could provide training in biology, medicine, pharmacy, chemistry, and related fields, while Academy institutes offered advanced research topics and instruments. This arrangement also helped doctoral students enter international science earlier. A student formally enrolled at a university could work in an Academy laboratory, publish with Academy researchers, access infrastructure, and participate in European projects. The outcome was not a merger but an interdependence. The Academy remained a public research institution, and the university remained an educational institution, but their functions overlapped in the formation of scientific careers and research programmes. This overlap was one of the most important post-1993 changes in Czech life-science organisation (*BIOCEV, n.d.; Charles University, n.d.*).

Cooperation with other universities also became essential. Palacký University in Olomouc played a major role through the Institute of Molecular and Translational Medicine, which became the national node of EATRIS-CZ. Masaryk University and CEITEC in Brno contributed to biomedical, molecular, and technological research capacities. The University of South Bohemia in České Budějovice formed a close regional ecosystem with the Biology Centre CAS, especially in ecology, parasitology, entomology, hydrobiology, and plant science. Czech University of Life Sciences and other institutions were important for agriculture, environment, plant biology, and applied ecological research. This wider network shows that Academy-university cooperation was not limited to Prague. Life sciences in the Czech Republic became geographically distributed. Prague remained central, but Brno, Olomouc, České Budějovice, and other centres gained strategic importance. This distribution was beneficial because different fields require different environments. Biomedicine needs hospitals and translational platforms; ecology needs field sites and regional biological expertise; plant and agricultural science need experimental landscapes and applied partners. The Academy's cooperation with universities therefore helped build a national life-science map rather than a single metropolitan cluster (*EATRIS-CZ, n.d.; Biology Centre CAS, n.d.*).

The Biology Centre CAS illustrates the regional dimension of this cooperation particularly well. Located in České Budějovice, it brought together institutes in entomology, hydrobiology, parasitology, plant molecular biology, and soil biology and biogeochemistry. Its relationship with the University of South Bohemia created a powerful scientific environment in South Bohemia. This cooperation was different from the biomedical model of BIOCEV, but no less important. It linked Academy research with university training in ecology, evolutionary biology, parasitology, plant science, and environmental biology. Field stations, freshwater systems, forests, ponds, soils, insect collections, and tropical ecology projects became part of a training and research ecosystem. The South Bohemian model shows that applied life sciences are not only about hospitals and pharmaceutical innovation. They also concern water quality, biodiversity, agriculture, parasitic disease, ecological monitoring, and environmental management. Academy-university cooperation in this region allowed organismal and ecological expertise to be reproduced across generations. It also gave regional science

international visibility, especially in tropical ecology, parasitology, freshwater ecology, and biodiversity research (*Biology Centre CAS, n.d.; University of South Bohemia, n.d.*).

Hospitals entered the Academy's life-science networks in a different way. Their primary role was not general education but clinical reality. Hospitals know what diseases look like in patients, what diagnostic gaps exist, what therapies fail, which samples are available, which ethical rules must be observed, and which interventions are realistic. Academy institutes, by contrast, are strongest in mechanism, method, model, and long-term experimental work. Translational research requires both. A molecular marker discovered in a laboratory has limited value unless it can be tested in clinical material and related to patient outcomes. A therapeutic candidate requires preclinical and clinical development. A biomaterial may need surgeons, rehabilitation specialists, regulatory experts, and clinical validation. Cooperation with hospitals therefore moved Academy biomedical research closer to the human consequences of disease. This did not turn Academy laboratories into hospital departments. Rather, it connected upstream science with downstream need. In the post-1993 period, such connections became increasingly formalised through infrastructures, projects, and translational networks, especially EATRIS-CZ (*EATRIS-CZ, n.d.; Institute of Experimental Medicine of the CAS, n.d.*).

EATRIS-CZ became one of the most important platforms linking Academy institutes, universities, hospitals, and clinical research. As the Czech national node of the European Infrastructure for Translational Medicine, it connected leading national research institutions, universities, and hospitals and aimed to accelerate chemical, biomedical, and clinical research into clinical practice. Its network included institutions such as Palacký University, Charles University, Masaryk University, the Institute of Experimental Medicine of the CAS, the Institute of Microbiology of the CAS, the Institute of Organic Chemistry and Biochemistry of the CAS, and clinical centres including St Anne's University Hospital Brno. This structure is historically significant because it institutionalised cooperation along the translational value chain. It recognised that biomedical innovation cannot move from discovery to patient through isolated enthusiasm. It requires preclinical platforms, clinical expertise, patient cohorts, diagnostics, regulatory knowledge, data systems, and industrial awareness. EATRIS-CZ therefore gave Czech biomedical research a practical framework for cooperation with hospitals and clinical researchers. For the Academy, participation in this network meant that its discoveries and platforms could be positioned within a broader route towards medical use (*EATRIS-CZ, n.d.; Institute of Microbiology of the Czech Academy of Sciences, n.d.*).

The presence of hospitals in such networks also changed the epistemology of biomedical research. Laboratory disease models are indispensable, but they are simplified. Patients are heterogeneous, affected by age, sex, environment, comorbidities, genetic background, lifestyle, and treatment history. A mechanism that appears clear in a cell line or animal model may become more complicated in clinical reality. Hospital cooperation therefore tests the robustness of laboratory knowledge. It also introduces researchers to questions that may not arise from model systems alone. Why do some patients fail to respond to therapy? Which diagnostic markers are actually useful in routine practice? How can a discovery be translated into a test that clinicians can use? What ethical and logistical barriers affect sample collection? These questions force Academy researchers to think beyond the controlled conditions of the laboratory. This is not a weakening of science, but an expansion of its relevance. It makes biomedical research more difficult and more realistic at the same time (*EATRIS, n.d.; EATRIS-CZ, n.d.*).

Cooperation with hospitals also encouraged the development of precision and personalised medicine. Contemporary biomedicine increasingly seeks to understand not only disease categories, but also subgroups of patients defined by molecular profiles, biomarkers, imaging, genetics, immune state, or therapeutic response. This requires a dense connection between laboratory science and clinical data. EATRIS-CZ's emphasis on translational infrastructure, patient cohorts, and clinical proof-of-concept belongs to this shift. Academy institutes could contribute molecular mechanisms, preclinical models, imaging platforms, chemical probes, bioinformatics, and biomaterials, while hospitals and university medical faculties provided the clinical environment in which patient relevance could be tested. This form of cooperation was especially important for oncology, infectious disease, neurodegeneration, regenerative medicine, and rare or complex disorders. Precision medicine therefore became one of the arenas where the Academy's basic research capacity and hospital-based clinical expertise met most directly. It also showed that cooperation was not merely institutional convenience, but a scientific requirement of modern medicine (*EATRIS, n.d.; Institute of Experimental Medicine of the CAS, n.d.*).

Industry formed the third major partner in the applied life-science triangle. Its role differed from that of universities and hospitals. Industry can develop products, manufacture at scale, navigate regulatory approval, conduct late-stage development, organise distribution, and invest in risky translational pathways. In biotechnology and biomedicine, these capacities are essential because many promising academic discoveries require years of development before they can reach users. Yet cooperation with industry also raises difficult questions. How can a public research institution protect academic freedom while engaging in commercial development? How should intellectual property be managed? How can conflicts of interest be avoided? How can public benefit be preserved when private companies are involved? The Academy's post-1993 life-science history shows a gradual movement towards professional answers to these questions. Instead of relying only on informal contacts, institutes developed technology-transfer offices, licensing structures, spin-off support, and investment partnerships. Industry cooperation became more systematic, but also more regulated and strategically selective (*IOCB Tech, n.d.; IOCB Prague, n.d.*).

The Institute of Organic Chemistry and Biochemistry became the most influential Academy model for industry cooperation. Its collaboration with Gilead Sciences, rooted in the antiviral discoveries associated with Antonín Holý and colleagues, demonstrated how a Czech public research institute could interact successfully with a global pharmaceutical company. The significance of this case lies not only in the drugs that emerged, but also in the institutional lessons it provided. Licensing, patent protection, long-term partnership, and reinvestment of revenues into research became part of the institute's development. The Gilead Sciences Research Centre at IOCB Prague showed that industry cooperation could support academic research rather than simply extract value from it. This model helped change attitudes within Czech science. It demonstrated that commercial partnership is not inherently opposed to scientific excellence when it is based on strong discovery, competent negotiation, and institutional control of intellectual property. The IOCB case became a reference point for the wider Academy and for Czech life-science innovation more generally (*IOCB Prague, n.d.; Gilead Sciences, 2006*).

IOCB Tech professionalised this industry-facing function. As the technology-transfer subsidiary of IOCB Prague, it identified commercially promising research results, assessed market potential and patentability, protected intellectual property, supported development,

searched for partners, and negotiated licensing agreements. These activities changed the practical meaning of cooperation with industry. Rather than individual scientists approaching companies ad hoc, a specialised organisation could mediate between academic research and commercial development. This mediation was crucial because scientists and companies often speak different languages. Scientists think in terms of mechanisms, methods, publications, and scientific novelty. Companies think in terms of protectable assets, markets, development risks, regulatory pathways, and investment. IOCB Tech helped translate between these worlds. Its existence also protected researchers from premature disclosure, poorly structured agreements, or unrealistic expectations. In the institutional history of the Academy, this kind of transfer office marks the maturation of applied research from occasional success to repeatable professional practice (*IOCB Tech, n.d.; IOCB Prague, n.d.*).

i&i Prague extended the cooperation model from licensing to venture building and spin-off development. Founded in 2017, it represented IOCB Prague in spin-off companies arising from the institute and also searched for innovative projects beyond IOCB, offering pre-seed financing and business expertise. This was important because not all life-science discoveries are best developed through direct licensing to an established company. Some require the creation of a new company that can focus on the technology, raise capital, build a team, and carry the project through early development. Spin-offs are especially common in biotechnology, diagnostics, drug discovery, and medical technologies, where early-stage academic results may be too specialised or too risky for large firms at first. i&i Prague therefore expanded the Academy-linked innovation ecosystem. It allowed public research results to enter entrepreneurial pathways while still drawing on scientific credibility and institutional experience. This development also showed that the Academy's cooperation with industry was no longer limited to external companies; it could involve the creation of new companies from academic knowledge (*i&i Prague, n.d.; IOCB Prague, 2017*).

The i&i Biotech Fund further broadened this cooperation by connecting academic life-science projects with investment capital. Established in cooperation with the European Investment Fund, it provided financing for academic spin-offs and innovative biotechnology projects. This kind of funding is essential because the gap between a promising discovery and an investable product is often difficult to cross. Traditional grants may support research, but they are not designed for business development. Large companies may wait until the risk is lower. Venture funds and specialised incubators can support the intermediate stage, where a technology must be de-risked, validated, protected, and positioned for further investment. The creation of such a fund reflected the growing sophistication of Czech bioinnovation. It also showed how Academy-linked structures entered a European financial environment. Cooperation with industry was no longer only bilateral; it became ecosystemic, involving public institutes, universities, start-ups, investors, European funds, and multinational partners (*i&i Prague, n.d.; CzechInvest, 2021*).

Industry cooperation was not limited to pharmaceuticals. Biotechnology, diagnostics, imaging, chemical biology, biomaterials, agricultural biotechnology, microbial products, environmental technologies, software, and data platforms all offered possible industrial connections. The Institute of Macromolecular Chemistry could cooperate around biomaterials, polymers, and medical or environmental materials. The Institute of Microbiology could connect with biotechnology, natural products, microbial processes, and industrial microbiology. The Institute of Experimental Botany could support plant biotechnology, crop resilience, and diagnostic methods for plant health. The Institute of Molecular Genetics could offer screening,

phenogenomics, imaging, and molecular tools. The Institute of Biotechnology could develop biomedical molecular tools and biotechnological methods. This diversity is important because it prevents the history of Academy-industry cooperation from being reduced to the IOCB–Gilead success story alone. That story is important, but the broader life-science ecosystem involved many possible routes from research to use. Some routes led to companies; others led to services, licences, public-sector tools, or collaborative projects (*Institute of Microbiology of the Czech Academy of Sciences, n.d.; Institute of Macromolecular Chemistry of the CAS, n.d.; Institute of Experimental Botany of the Czech Academy of Sciences, n.d.*).

Research infrastructures became one of the main meeting points between the Academy, universities, hospitals, and industry. Czech-BioImaging, CZ-OPENSCREEN, the Czech Centre for Phenogenomics, ELIXIR CZ, and EATRIS-CZ offered services and expertise to academic and sometimes non-academic users. This service orientation changed the Academy's relationship with external partners. Instead of cooperation depending only on personal scientific contacts, partners could access defined facilities, technologies, methods, and expert support. An industrial partner might need screening or imaging. A hospital-linked group might need preclinical models. A university laboratory might need sequencing, phenotyping, or bioinformatics. A biotechnology start-up might need validation services. Infrastructures therefore acted as interfaces between institutions. They made cooperation more systematic, transparent, and technically reliable. They also placed Academy institutes within European norms of open access, quality control, and shared capacity. In the applied life sciences, such infrastructures are often as important as individual discoveries because they create the conditions under which discoveries can be tested and developed (*Czech-BioImaging, n.d.; CZ-OPENSCREEN, n.d.; Czech Centre for Phenogenomics, n.d.; ELIXIR CZ, n.d.*).

EATRIS-CZ is especially important because it explicitly joined research institutions, universities, hospitals, and translational development. It provided a framework for moving from discovery towards clinical proof-of-concept and first-in-human application, particularly through product platforms for drugs, vaccines, diagnostics, and advanced therapies. Academy institutes within this network could contribute their strongest capacities while relying on clinical partners for patient-related expertise. The Institute of Experimental Medicine, for example, contributed expertise relevant to advanced therapy medicinal products, genetically modified organisms, embryonic stem cells, and experimental animals. The Institute of Microbiology contributed applied and basic microbiological capacities. IOCB contributed chemical and medicinal expertise. This networked arrangement shows that translational medicine is not a single institutional possession. It is a chain of capabilities spread across institutions. The Academy's role was to provide key links in that chain, especially in basic mechanisms, preclinical research, chemical biology, microbiology, biomaterials, and experimental models (*EATRIS-CZ, n.d.; Institute of Experimental Medicine of the CAS, n.d.; Institute of Microbiology of the Czech Academy of Sciences, n.d.*).

Cooperation also affected the governance of research. Joint projects require agreements on funding, authorship, intellectual property, data sharing, ethics, access to facilities, and responsibility for results. These issues are more complex when universities, hospitals, and companies are all involved. A university may prioritise publication and student training. A hospital may prioritise patient welfare and clinical utility. A company may prioritise protectable assets and development timelines. An Academy institute may prioritise scientific excellence and long-term research continuity. Successful cooperation requires mechanisms that allow these priorities to be aligned without pretending they are identical. Post-1993 Czech life

sciences gradually developed such mechanisms through contracts, infrastructure access rules, technology-transfer offices, ethics committees, and project-management structures. This was a major institutional change. Cooperation was no longer a matter of informal socialist-era personal networks or ad hoc bilateral arrangements. It became a professionalised part of research governance (*IOCB Tech, n.d.; EATRIS, n.d.*).

The ethical dimension of cooperation was particularly important in biomedical research. Work with hospitals involves patients, samples, medical data, clinical uncertainty, and public expectations. Work with industry involves commercial interests, intellectual property, and possible conflicts of interest. Work with animal models, stem cells, genetic technologies, and advanced therapies raises additional ethical questions. The Academy's cooperation with external partners therefore had to be grounded in responsible research standards. Ethical review, informed consent, data protection, animal welfare, transparency in funding, and scientific integrity became essential elements of cooperation. This is historically significant because it shows how post-1993 autonomy differed from the older struggle against political control. Scientific freedom now had to coexist with accountability to patients, society, collaborators, and international norms. Cooperation expanded the Academy's reach, but it also expanded its responsibilities. A public research institution cannot enter biomedical innovation as if it were only a private market actor. It must carry its public ethos into every partnership (*EATRIS, n.d.; Czech Academy of Sciences, n.d.*).

Cooperation with industry also required a realistic understanding of failure. Many academic discoveries do not become products, even when they are scientifically valuable. Clinical development may fail, markets may be too small, toxicity may appear, manufacturing may be difficult, or a competing technology may advance faster. This reality affects relationships among institutes, universities, hospitals, and companies. If cooperation is judged only by immediate commercial success, it will appear disappointing. A more mature view recognises that partnerships can produce several kinds of value: publications, patents, trained personnel, methods, data, validated models, improved diagnostics, clinical insight, failed-but-informative trials, and new companies. The Academy's life-science cooperation after 1993 should therefore be evaluated as ecosystem building rather than as a catalogue of products. The IOCB antiviral success was exceptional, not routine. Its importance lies partly in showing what is possible, but it should not create the illusion that every cooperation can produce similar outcomes. Sustainable cooperation depends on accepting uncertainty while building structures that improve the probability of useful results (*IOCB Prague, n.d.; EATRIS-CZ, n.d.*).

Internationalisation strengthened all three forms of cooperation. Universities, hospitals, and industry partners were increasingly connected through European projects, research infrastructures, mobility programmes, and multinational development networks. EATRIS-CZ linked Czech institutions to a European infrastructure with many academic centres across Europe. CZ-OPENSCREEN connected chemical biology to European screening environments. Czech-BioImaging aligned national imaging facilities with European standards. IOCB's partnerships connected Czech chemistry with global pharmaceutical and biotechnology systems. This internationalisation mattered because life-science innovation is rarely purely national. A Czech discovery may need European validation, American investment, multinational clinical development, or global regulatory strategy. International networks also raised standards. Czech institutions had to make their methods, data, ethics, and project management compatible with partners abroad. This increased the quality of cooperation at home as well. Domestic Academy-university-hospital-industry relations became more

professional partly because they had to operate within international frameworks (*EATRIS, n.d.; CZ-OPENSCREEN, n.d.; Czech-BioImaging, n.d.; IOCB Prague, 2024*).

The COVID-19 pandemic provided an unexpected stress test of these cooperative networks. Academy institutes, universities, hospitals, technology-transfer structures, and public-health authorities worked together on testing, diagnostics, protective materials, modelling, and expert communication. BIOCEV's laboratories were repurposed for PCR testing in cooperation with Charles University and Academy institutes. IOCB Tech supported diagnostic-test development. Academy researchers contributed to molecular surveillance and public interpretation. The pandemic demonstrated that cooperation built for research and innovation could become cooperation for crisis response. It also showed that public health relies on pre-existing relationships. Institutions cannot easily invent trust, protocols, or technical capacity in the middle of an emergency. The pandemic therefore confirmed the strategic importance of cooperation among universities, hospitals, industry, and the Academy. These relationships were not only useful for long-term innovation; they were part of national resilience (*Academy of Sciences of the Czech Republic, 2020; BIOCEV Gene Core, 2020*).

The role of doctoral and postdoctoral researchers should not be overlooked. Cooperation among institutions is often described at the level of directors, agreements, centres, and infrastructures, but much of it is lived by early-career scientists. A doctoral student may be enrolled at Charles University, trained in an Academy laboratory, use a national infrastructure, collaborate with a hospital group, and later join a biotechnology company or spin-off. A postdoctoral researcher may move between an Academy institute, a European project, and an industrial partner. These career trajectories are themselves mechanisms of cooperation. People carry methods, norms, and contacts across institutional boundaries. After 1993, such mobility became one of the ways Czech life sciences overcame the older rigidity of the research system. Cooperation was not only written into agreements; it was embodied in scientific biographies. This generational dimension was essential for innovation because new fields often emerge when young researchers move fluently between academic, clinical, and industrial contexts (*BIOCEV, n.d.; EATRIS-CZ, n.d.*).

The cooperation model also changed the public image of the Academy. A self-contained academy may appear distant from ordinary social needs, even when it produces excellent science. An academy that cooperates with universities, hospitals, and industry can show more clearly how public research enters education, health, technology, and the economy. This does not mean that public visibility should determine all research priorities. Some of the most valuable discoveries remain invisible for years. Yet cooperation helps society understand the routes by which knowledge becomes useful. A molecule studied at IOCB may become a licensed therapy. A model developed at the Czech Centre for Phenogenomics may support disease research. A biomaterial from the Institute of Macromolecular Chemistry may lead towards regenerative medicine. A diagnostic method developed with hospital partners may improve patient stratification. A plant-biotechnology result may support agriculture. Such examples make the Academy's public value concrete. They also help justify stable funding for basic research, because they show that application grows from long-term scientific depth rather than from short-term political pressure (*IOCB Prague, n.d.; Strategy AV21, n.d.*).

Cooperation with universities, hospitals, and industry also had limits. Institutional cultures differ, and conflict is unavoidable. Universities may be concerned about academic freedom and student training. Hospitals may prioritise immediate clinical demands over research

timelines. Industry may seek exclusivity, speed, and commercial confidentiality. Academy institutes may need time for basic inquiry and publication. Public funders may demand measurable impact. These pressures can create misunderstandings. Cooperation is therefore not an inherently harmonious process. It requires negotiation, governance, trust, and sometimes restraint. The Academy's post-1993 experience shows that successful cooperation depends on recognising differences rather than pretending they do not exist. A strong public research institution should cooperate widely but not lose its core identity. Its role is not to become a university, hospital, or company, but to connect with them from the position of scientific depth and institutional autonomy (*Czech Academy of Sciences, n.d.; IOCB Tech, n.d.*).

By the 2020s, cooperation had become one of the defining features of Czech Academy life sciences. BIOCEV institutionalised Academy-university collaboration. EATRIS-CZ linked Academy institutes with universities, hospitals, and translational platforms. IOCB Tech, i&i Prague, and the i&i Biotech Fund connected academic discoveries with industry and investment. Czech-BioImaging, CZ-OPENSCREEN, ELIXIR CZ, and the Czech Centre for Phenogenomics offered shared capacities across institutional boundaries. The Biology Centre and the University of South Bohemia showed the strength of regional research ecosystems. Charles University, Palacký University, Masaryk University, CEITEC, university hospitals, and industrial partners all became part of the wider life-science network. This network did not erase the Academy's individuality. Instead, it made that individuality more productive. The Academy's institutes could remain centres of long-term research while participating in the applied, clinical, educational, and industrial environments necessary for contemporary life sciences (*BIOCEV, n.d.; EATRIS-CZ, n.d.; i&i Prague, n.d.*).

Thus, cooperation with universities, hospitals, and industry after 1993 became a central mechanism through which the Academy of Sciences of the Czech Republic transformed life-science research into a modern, networked, and application-capable system. Universities helped connect Academy research with doctoral training, disciplinary breadth, and academic reproduction. Hospitals linked laboratory discoveries to clinical reality, patient needs, diagnostics, and therapeutic validation. Industry provided development capacity, intellectual-property pathways, investment, manufacturing potential, and routes to wider use. The Academy contributed what it could do best: fundamental knowledge, specialised institutes, long-term continuity, advanced infrastructures, and scientific credibility. BIOCEV, EATRIS-CZ, IOCB Tech, i&i Prague, the i&i Biotech Fund, Czech-BioImaging, CZ-OPENSCREEN, ELIXIR CZ, the Czech Centre for Phenogenomics, and regional ecosystems such as the Biology Centre and the University of South Bohemia all demonstrate that cooperation became institutional rather than occasional. This history shows that post-1993 Czech life sciences did not move from autonomy to dependence, but from isolated autonomy to connected autonomy. The Academy remained itself, but it became more useful, more visible, and more resilient because it learned to work systematically with the institutions through which knowledge becomes education, diagnosis, therapy, technology, and innovation.

3. The Place of Life Sciences in the Innovation Ecosystem

After 1993, the life sciences gradually became one of the most important bridges between the Academy of Sciences of the Czech Republic and the emerging Czech innovation ecosystem. This did not happen immediately, nor did it occur through a simple conversion of research

institutes into commercial laboratories. The Academy entered the post-socialist period with a strong tradition of public, institute-based research, but with comparatively weaker experience in market-oriented technology transfer, venture financing, intellectual-property management, and industrial innovation under democratic capitalism. The life sciences forced these issues to the surface because biological and biomedical discoveries often possess visible social and economic potential. A molecule may become an antiviral drug, a biomarker may become a diagnostic tool, a genetic model may support preclinical research, a polymer may become a biomaterial, a plant-biotechnology method may support agriculture, and ecological expertise may guide environmental management. Yet none of these applications emerges automatically from discovery. They require an ecosystem: institutions, funding instruments, infrastructures, companies, regulatory standards, public policies, universities, hospitals, investors, and trained people. The place of life sciences in the Czech innovation ecosystem after 1993 was therefore defined by a dual movement. On the one hand, Academy institutes preserved fundamental research as their primary source of strength. On the other hand, they increasingly developed the mechanisms through which selected results could move towards social, medical, environmental, and economic use (*Czech Academy of Sciences, n.d.; IOCB Prague, n.d.*).

The concept of an innovation ecosystem is useful because it avoids the misleading idea that innovation is produced by one institution alone. In the life sciences, innovation almost always depends on multiple actors. A public research institute may discover a mechanism, compound, material, organismal model, or diagnostic principle. A university may train the researchers who carry that discovery forward. A hospital may test its relevance to patients. A technology-transfer office may protect the intellectual property. A start-up may develop the idea into a platform. An investor may finance the risky early stage. A company may manufacture or commercialise the product. A regulator may approve or reject its use. A public agency may create incentives or infrastructure support. European programmes may provide funding and standards. This chain is not linear, because ideas often move back and forth between research and development. It is better understood as an ecosystem in which knowledge circulates through several institutional environments. The Academy's life sciences became increasingly important in this ecosystem because they provided the deep research base without which the later stages would be empty. Their role was foundational rather than merely supplementary (*EATRIS, n.d.; EATRIS-CZ, n.d.*).

In the Czech case, the post-1993 innovation ecosystem developed under specific historical constraints. The country possessed strong scientific schools, a highly educated population, industrial traditions, and excellent institutes, but it also inherited from state socialism a research system that had not been organised around competitive entrepreneurship. Applied research had existed before 1989, but it operated within a planned economy and state-sector logic. After 1993, the Academy and the wider Czech research system had to adapt to patents, licensing, private firms, foreign investment, European research programmes, and global competition. This adaptation was uneven. Some fields moved faster than others. Organic chemistry, medicinal chemistry, molecular biology, biotechnology, and biomedical infrastructures created visible successes, while other areas required longer cultural and institutional learning. The life sciences were both a challenge and an opportunity. They demanded expensive infrastructure and sophisticated transfer mechanisms, but they also offered some of the clearest examples of how Czech basic research could generate international value. The Academy's position in the innovation ecosystem therefore grew from

the interaction between inherited scientific excellence and newly built innovation institutions (*IOCB Prague, n.d.; CzechInvest, 2021*).

The Institute of Organic Chemistry and Biochemistry became the most visible institutional model for this transition. Its antiviral discoveries showed that public research in chemistry and biology could lead to therapies of global importance. The institute's later technology-transfer strategy, including IOCB Tech, the Gilead Sciences Research Centre, i&i Prague, and IOCB Boston, placed it at the centre of Czech bioinnovation. IOCB's example mattered not because every Academy institute could reproduce the same financial or pharmaceutical success, but because it demonstrated the institutional possibility of turning basic research into protected, developed, and internationally valuable assets. It also showed that application does not weaken basic research when the relationship is managed wisely. Revenues, partnerships, and transfer structures can support further discovery rather than replace it. This was an important lesson for the Academy as a whole. The old opposition between pure science and practical application became less convincing. The more serious question became how to build institutions capable of protecting both excellence and transfer potential (*IOCB Prague, n.d.; IOCB Tech, n.d.; i&i Prague, n.d.*).

The life-science innovation ecosystem also depended on research infrastructures. In contemporary biotechnology and biomedicine, laboratories cannot move towards application without access to specialised platforms. Czech-BioImaging, CZ-OPENSCREEN, the Czech Centre for Phenogenomics, ELIXIR CZ, BIOCEV, and EATRIS-CZ all contributed to this infrastructural layer. Imaging makes cellular and tissue processes visible. Screening identifies probes and candidate compounds. Phenogenomics validates gene function and disease models. Bioinformatics manages biological data. BIOCEV provides a shared biotechnology and biomedicine environment. EATRIS-CZ links chemical, biomedical, and clinical research to translational medicine. These infrastructures are not merely technical appendices to scientific work. They shape what can be discovered, measured, validated, and developed. They also serve users beyond the originating institute, creating interfaces among Academy institutes, universities, hospitals, and companies. The Academy's life-science role in the innovation ecosystem therefore rested not only on individual discoveries but on the provision of national and European scientific capacity (*BIOCEV, n.d.; Czech-BioImaging, n.d.; CZ-OPENSCREEN, n.d.; Czech Centre for Phenogenomics, n.d.; ELIXIR CZ, n.d.; EATRIS-CZ, n.d.*).

The Czech Centre for Phenogenomics illustrates this infrastructural contribution particularly well. Modern disease research and biomedical innovation require model organisms that can connect genetic discoveries with organismal function. A gene identified in a sequencing study or a pathway observed in cells needs validation in living systems before it can plausibly support therapy or diagnostics. Phenogenomics provides this bridge through genetically modified mouse and rat models, standardised phenotyping, imaging, pathology, cryopreservation, data analysis, and preclinical services. Such capacity is valuable not only for Academy laboratories but also for universities, hospitals, biotechnology companies, and international collaborators. It reduces the distance between basic biology and development-ready knowledge. In ecosystem terms, it functions as shared infrastructure that lowers barriers for many actors. This is one of the ways in which a public research institution can strengthen innovation without becoming a private company. It provides capabilities that the market alone might under-supply because they are expensive, specialised, and useful across many projects (*Czech Centre for Phenogenomics, n.d.; INFRAFRONTIER, n.d.*).

CZ-OPENSCREEN offers another example of the Academy's position at the early stage of innovation. Chemical biology occupies the space between mechanism and intervention. Small molecules can be used to probe pathways, validate targets, reveal vulnerabilities, and begin therapeutic exploration. Most such molecules will not become drugs, but they are essential for understanding whether a biological process can be manipulated. CZ-OPENSCREEN, hosted by the Institute of Molecular Genetics, provides access to compound libraries, screening technologies, assay expertise, and chemical-biology support. This is an ecosystem function because it helps academic groups generate more mature and testable results before seeking industrial development. It also supports companies that need specialised screening capacity. The infrastructure therefore creates a shared zone between public research and bioinnovation. It shows that the Academy's role is not only to discover knowledge, but also to make early-stage development scientifically credible (*CZ-OPENSCREEN, n.d.; Research Infrastructures of the Czech Republic, n.d.*).

BIOCEV's place in the innovation ecosystem is broader and more spatial. As a joint biotechnology and biomedicine centre of the Academy and Charles University, it created a campus environment in which basic research, doctoral training, infrastructure, and applied potential could coexist. Its significance lies in its ability to concentrate critical mass. Innovation in the life sciences rarely emerges from isolated brilliance alone. It requires proximity among molecular biologists, structural biologists, microbiologists, geneticists, chemists, physicians, bioinformaticians, students, facility specialists, and transfer professionals. BIOCEV gave Czech life sciences one of the environments where such proximity could be sustained. It also helped connect the Academy with university education and biomedical training. In ecosystem terms, BIOCEV functioned as a node where the traditional separation between Academy institutes and university faculties became more porous. This porosity was essential because innovation depends on movement: of people, ideas, samples, data, methods, and technologies (*BIOCEV, n.d.; Institute of Molecular Genetics of the Czech Academy of Sciences, 2015*).

EATRIS-CZ linked the Academy's biomedical research with clinical translation and hospital environments. This was crucial because life-science innovation often fails at the boundary between laboratory and clinic. A promising biomarker, compound, material, or biological mechanism must be tested in relation to real patients, clinical workflows, regulatory pathways, and therapeutic needs. EATRIS-CZ connected research institutions, universities, and hospitals to support chemical, biomedical, and clinical research and speed its transfer into clinical practice. Academy institutes such as the Institute of Experimental Medicine, Institute of Microbiology, and Institute of Organic Chemistry and Biochemistry belonged to this wider translational landscape. The ecosystem function here was clear. EATRIS-CZ helped organise the difficult middle space between discovery and clinical use. It did not turn every discovery into a therapy, but it created a framework in which promising results could be evaluated, validated, and moved forward more systematically. This was one of the most important changes in Czech biomedical innovation after 1993 (*EATRIS, n.d.; EATRIS-CZ, n.d.*).

The state also shaped the life-science innovation ecosystem through policy and funding. The National Research and Innovation Strategy for Smart Specialisation, or RIS3, directed support towards priority areas with potential to create long-term competitive advantage through knowledge exploitation and innovation. This mattered for the Academy because public research organisations operate within national strategies even when they retain scientific autonomy. Life sciences, biotechnology, pharmaceuticals, diagnostics, medical technologies,

and related fields became part of the Czech Republic's ambition to strengthen knowledge-based competitiveness. CzechInvest's Tech4Life framing similarly presented the life-science sector as supported by patent protection, GMP, GLP and GCP standards, genetic-engineering regulation aligned with the European environment, R&D infrastructure, and government support for knowledge transfer between science and business. Such policy language shows that life sciences were no longer viewed only as academic disciplines. They became part of industrial, health, and competitiveness policy. The Academy's role was to supply the research depth and credibility that such policy ambitions required (*National RIS3 Strategy, 2021; CzechInvest, n.d.*).

The Czech innovation ecosystem also included national agencies and support instruments beyond the Academy itself. CzechInvest, Technology Incubation, venture funds, regional innovation centres, university transfer offices, and European programmes all contributed to the environment in which Academy discoveries could move towards application. Technology Incubation, for example, aimed to support innovative technology companies and develop the start-up ecosystem in strategic sectors. Such instruments are important because the life sciences require more than excellent science. They need entrepreneurship, mentoring, investment readiness, regulatory planning, and access to markets. For Academy-linked projects, these instruments could provide routes beyond the institute. At the same time, the Academy's contribution remained distinctive. It was not an incubator, investment agency, or ministry. Its value lay in producing high-quality knowledge and infrastructural capacity that other actors could help translate. The innovation ecosystem worked best when each actor understood its own function and cooperated without trying to replace the others (*CzechInvest, 2022; Technology Incubation, n.d.*).

The emergence of i&i Prague and the i&i Biotech Fund strengthened the entrepreneurial side of Czech life sciences. i&i Prague acted as a biotech incubator and venture builder, supporting spin-offs and early-stage academic projects. The i&i Biotech Fund focused on European life-science companies in areas such as drug discovery, medtech, diagnostics, and artificial intelligence. This was significant because early-stage biotechnology often suffers from a funding gap. Academic grants may support discovery, but they rarely provide the resources needed for company formation, regulatory planning, proof-of-concept development, or investor engagement. Large pharmaceutical companies may not enter until the risk is lower. Specialised venture funds and incubators can occupy this difficult middle zone. Their emergence around IOCB and the wider Czech academic environment indicates that life sciences had become one of the few areas where Czech research could plausibly generate a more complete innovation chain. For the Academy, this meant that its discoveries could enter entrepreneurial pathways without forcing research institutes themselves to become commercial firms (*i&i Prague, n.d.; i&i Bio, n.d.; CzechInvest, 2021*).

The place of life sciences in the innovation ecosystem was also strengthened by internationalisation. Czech biotechnology and biomedical research could not rely solely on the domestic market. The country's scientific capacity was strong, but the scale of pharmaceutical development, venture capital, clinical validation, and global competition required international partners. IOCB Boston represented this recognition. By opening a branch in one of the world's leading biotechnology hubs, IOCB Prague positioned Czech academic projects closer to American investors, companies, and development networks. European infrastructures and EU programmes performed a similar function at the continental level. They connected Czech laboratories to shared standards, facilities, data systems, clinical networks,

and funding streams. The result was a multi-level ecosystem: Czech in institutional roots, European in policy and infrastructure, and global in application potential. This international structure was not a luxury. In life sciences, serious innovation almost always depends on cross-border development pathways (*IOCB Prague, 2024; European Commission, 2025*).

The innovation ecosystem also redefined the relationship between public and private value. Life-science discoveries can produce commercial products, but their public meaning is broader. An antiviral medicine, diagnostic test, biomaterial, disease model, biodiversity database, plant-resilience tool, or microbial technology may serve society in ways that cannot be measured only by revenue. The Academy's public character made this distinction important. It had to participate in commercialisation where appropriate, but it also had to defend research whose value was social, medical, environmental, or strategic rather than immediately profitable. Strategy AV21 expressed this broader orientation through the motto of top research in the public interest. Its programmes linked Academy institutes with universities, industry, the state, and the public sector around contemporary societal challenges. This framework complemented technology transfer by reminding policymakers and researchers that innovation is not identical with commercialisation. Public-interest research can produce policy tools, expert advice, methods, infrastructures, standards, and long-term preparedness. In the life sciences, such outputs may be as important as market products (*Strategy AV21, n.d.; Czech Academy of Sciences, 2026*).

The life sciences therefore occupied a distinctive position between market innovation and public-good innovation. Biomedical compounds, diagnostics, and biotechnology platforms may move through patents, licences, spin-offs, investors, and companies. Ecological expertise, biodiversity monitoring, plant-health knowledge, public-health preparedness, and environmental risk assessment may move through public agencies, conservation authorities, agricultural practice, or international policy bodies. Both forms belong to the innovation ecosystem, but they operate through different channels. The Academy's life-science institutes participated in both. IOCB, IBT, IMG, and related biomedical infrastructures were strongly connected with commercial or translational pathways. The Institute of Botany, Biology Centre, Institute of Experimental Botany, and ecological institutes contributed to environmental and public-policy innovation. The Czech innovation ecosystem is therefore best understood not as a single market pipeline, but as a plural system of knowledge use. The Academy's institutional breadth allowed it to contribute to this plurality (*Institute of Botany of the Czech Academy of Sciences, n.d.; Biology Centre CAS, n.d.; Institute of Experimental Botany of the Czech Academy of Sciences, n.d.*).

The innovation ecosystem also depended on trust between researchers and non-academic partners. Scientists may fear that industry will restrict publication, distort priorities, or appropriate public knowledge. Companies may fear that academic partners lack development discipline, deadlines, or market awareness. Hospitals may fear that research projects will not respect clinical realities. Public agencies may fear that scientific recommendations will be too uncertain for policy use. Technology-transfer organisations, translational infrastructures, and joint centres help manage these tensions. They create rules, contracts, expectations, and shared processes. In post-1993 Czech life sciences, this trust had to be built gradually. It could not be inherited from the socialist system, where state ownership and planning had produced a very different kind of relationship between research and production. Trust in the new ecosystem required professional mediation, successful examples, and repeated cooperation.

The Academy's strongest cases, especially IOCB and BIOCEV, helped demonstrate that such trust was possible (*IOCB Tech, n.d.; BIOCEV, n.d.*).

The human dimension of innovation should not be underestimated. Life-science ecosystems are built by people who can move between institutional cultures. Doctoral students, postdoctoral researchers, facility managers, technology-transfer officers, clinician-scientists, entrepreneurs, project managers, patent lawyers, investors, and public-policy experts all contribute to the route from discovery to use. After 1993, Czech Academy institutes became increasingly involved in training such people, even when formal degrees remained the responsibility of universities. A student trained in an Academy laboratory may later work in a hospital research unit, a biotechnology start-up, a university department, a technology-transfer office, or an international company. These career paths are part of the innovation ecosystem because they carry knowledge across boundaries. The Academy's life-science institutes therefore contributed not only discoveries and infrastructures, but also human capital. This contribution is often less visible than a patent or a spin-off, but it is fundamental. Without trained people able to operate in different environments, innovation ecosystems remain institutional diagrams rather than living systems (*BIOCEV, n.d.; EATRIS-CZ, n.d.*).

The regional dimension also shaped the place of life sciences in innovation. Prague was central because of IOCB, Charles University, BIOCEV, IMG, and several major infrastructures. Brno was important through Masaryk University, CEITEC, the Institute of Biophysics, hospitals, and technological initiatives. Olomouc contributed through Palacký University and translational medicine. České Budějovice and South Bohemia were important for ecology, parasitology, freshwater biology, plant science, and the Biology Centre. This distributed geography mattered because innovation ecosystems are not only national; they are regional. Proximity among institutes, universities, firms, hospitals, and public agencies helps ideas move. At the same time, strong national and European networks prevent regional fragmentation. The Academy's life-science institutes contributed to this multi-centre geography. They helped ensure that Czech innovation was not reduced to one city or one sector. This regional spread also corresponded to the diversity of life sciences themselves, from biomedical laboratories to field ecology and agricultural landscapes (*CzechInvest, n.d.; Biology Centre CAS, n.d.*).

The life-science innovation ecosystem was also shaped by regulation and standards. Biomedical innovation requires Good Manufacturing Practice, Good Laboratory Practice, Good Clinical Practice, ethical review, animal-welfare rules, data protection, clinical-trial regulation, and patent law. Plant biotechnology and synthetic biology require biosafety rules and public communication. Environmental biotechnology requires ecological assessment and regulatory oversight. These standards can be burdensome, but they are also conditions of trust. A diagnostic test, therapy, biomaterial, or genetically modified tool cannot enter responsible use without validation and governance. CzechInvest's description of the life-science sector emphasised patent protection, GMP, GLP, GCP standards, and alignment with the European regulatory environment. For the Academy, this meant that practical application required partners and professionals who understood regulation. Scientists could not simply assume that a good result would move into use. Innovation had to be compatible with law, ethics, safety, and quality assurance (*CzechInvest, n.d.; EATRIS, n.d.*).

Synthetic biology illustrates both the promise and the sensitivity of life-science innovation. It combines biology, engineering, genetics, computation, and design-oriented thinking, and it can support medicine, materials, agriculture, environmental technologies, and industrial

processes. Yet it also raises questions of biosafety, public acceptance, ethical limits, and governance. Czech discussions of synthetic biology have recognised the need to build community, capacity, and public understanding. This is important because innovation ecosystems are not built only through investment and laboratories. They also depend on social legitimacy. Public uncertainty about genetic modification, biotechnology, or biological engineering can affect policy, funding, and adoption. The Academy's role includes not only research but also informed public dialogue. Life-science innovation must be explained, debated, and governed if it is to retain democratic legitimacy (*Juračka et al., 2024; Strategy AV21, n.d.*).

The Academy's place in the innovation ecosystem was therefore not the same as that of a private biotechnology company. A company must focus on development, product strategy, investment, and market success. The Academy must focus on knowledge, excellence, continuity, public responsibility, and the conditions that make future innovation possible. When it participates in technology transfer or spin-offs, it does so from this public-research identity. This distinction matters because the Academy's legitimacy would be weakened if it measured itself only by commercial outputs. Its strongest contribution to the ecosystem is the production of deep, reliable, and often long-term knowledge. Some of that knowledge becomes commercial. Some becomes public-health capacity. Some becomes environmental expertise. Some becomes training. Some becomes infrastructure. Some remains fundamental until future conditions reveal its usefulness. The Academy's innovation role is therefore broader than product generation. It is the cultivation of a knowledge base from which different forms of value can emerge (*Czech Academy of Sciences, n.d.; Strategy AV21, n.d.*).

The COVID-19 pandemic provided a dramatic demonstration of this broader ecosystem role. Molecular testing, diagnostic development, genomic surveillance, behavioural research, modelling, materials analysis, and technology-transfer support all became part of crisis response. Many of these capacities had been created for research and innovation before the crisis. The pandemic showed that life-science infrastructures and expertise can become public-health resilience. This experience changed the public meaning of innovation. Innovation was no longer only about competitiveness or start-ups; it was also about the ability of society to respond to emergency. Academy institutes contributed because they had maintained capacities that could be redirected quickly. The lesson for the innovation ecosystem was clear: long-term public research is a strategic reserve. It supports economic development in normal times and national resilience in crises (*Academy of Sciences of the Czech Republic, 2020; Šúri et al., 2025*).

The life sciences also exposed the limits of a narrow innovation policy. If policy focuses only on immediate commercialisation, it may neglect taxonomy, ecology, public health, basic physiology, long-term monitoring, or fundamental molecular mechanisms whose value appears later. If policy focuses only on publication metrics, it may neglect transfer, validation, public engagement, and user needs. The Academy's experience suggests that a mature innovation ecosystem must support multiple temporalities. Some projects move quickly to application; others require decades. Some require patents; others require open data. Some need industrial partners; others need public agencies or conservation authorities. Life sciences are diverse enough to make this plurality visible. The Academy's task was not to force all research into one innovation model, but to maintain an institutional environment where different routes to value could coexist (*National RIS3 Strategy, 2021; Strategy AV21, n.d.*).

By the 2020s, the Czech life-science innovation ecosystem had become more complete than it had been in the early 1990s. It included strong Academy institutes, research universities, modern infrastructures, university hospitals, technology-transfer offices, incubators, venture funds, European research networks, national strategies, and international partners. It also included weaknesses: limited domestic pharmaceutical scale, uneven venture capital compared with larger countries, administrative burdens, competition for talent, and the continuing difficulty of moving discoveries through expensive development phases. A serious institutional history must recognise both sides. The progress was substantial, but the ecosystem remained dependent on international links and long-term public investment. The Academy's life sciences occupied a central place in this system because they provided scientific depth, credibility, and continuity. Without them, the innovation ecosystem would be thinner, more dependent on imported knowledge, and less capable of producing original Czech contributions (*CzechInvest, n.d.; i&i Bio, n.d.; European Commission, 2025*).

The historical meaning of life sciences in the innovation ecosystem is therefore larger than biotechnology alone. It concerns the transformation of the Academy's relationship with society. In earlier chapters of the Academy's history, the central questions concerned national culture, state authority, ideological control, autonomy, and institutional survival. After 1993, these questions did not disappear, but they were joined by a new one: how can a public academy contribute to a knowledge-based democratic economy without losing the independence and depth that make it valuable? The life sciences offered one of the most persuasive answers. They showed that public research can produce discoveries, infrastructures, people, methods, companies, diagnostics, therapies, public-health capacity, environmental expertise, and policy-relevant knowledge. They also showed that such contributions require autonomy, not obedience to short-term political or market demand. The Academy's place in the innovation ecosystem was strongest when it remained scientifically ambitious and publicly accountable at the same time.

Thus, the place of life sciences in the innovation ecosystem after 1993 reveals the Czech Academy's movement from institute-based public research towards connected, application-capable, and internationally embedded knowledge production. Life sciences became a strategic field because they linked molecular discovery, biomedical need, environmental responsibility, biotechnology, public health, venture creation, research infrastructures, and European innovation policy. IOCB Prague, IOCB Tech, i&i Prague, i&i Bio, BIOCEV, EATRIS-CZ, CZ-OPENSCREEN, Czech-BioImaging, ELIXIR CZ, the Czech Centre for Phenogenomics, Strategy AV21, RIS3 priorities, CzechInvest initiatives, universities, hospitals, and industry all formed parts of this ecosystem. The Academy did not become an industrial corporation, and its strongest function remained the production of deep public knowledge. Yet it learned to create pathways through which knowledge could become diagnostics, therapeutics, materials, tools, companies, public expertise, and crisis capacity. This history shows that innovation in the life sciences is not a sudden leap from laboratory to market, but a long institutional process in which autonomy, infrastructure, policy, trust, capital, regulation, and scientific excellence must work together.

Chapter 12.

Humanities and Social Sciences: Memory, Society, Language, and Culture

The Humanities after Ideology

1. Rebuilding Historical, Philosophical, and Philological Research after 1989

The transformation of the humanities in the Czech lands after 1989 was not merely a change of institutional administration, nor only a correction of research plans imposed by the late socialist state. It was a deeper epistemic and moral reconstruction, because history, philosophy, philology, literary studies and linguistics had all been affected by the ideological architecture of the previous regime in different but interconnected ways. Some fields had been directly subordinated to Marxist-Leninist interpretation, others had survived by cultivating older scholarly traditions in restricted or formally neutral spaces, and still others had preserved intellectual continuity through source editions, dictionaries, textual criticism, archival work and specialised historical research. The Velvet Revolution therefore opened not an empty field, but a complicated landscape in which suppressed traditions, compromised institutions, returning émigrés, internally marginalised scholars and younger researchers had to find a new common language. In this sense, the rebuilding of the humanities was both institutional and biographical: institutes had to be reorganised, but scholarly careers, intellectual reputations and ethical responsibilities also had to be reassessed. The humanities were expected to help society understand the past, yet they themselves had been part of that past and could not simply speak from outside it. This made the post-1989 renewal of the Academy's humanities unusually delicate, because it joined the language of academic freedom with the language of public accountability (*Kopeček & Kolář, 2007*; *Franc & Mádlová, 2014*).

The first task after 1989 was to restore autonomy where ideological supervision had earlier shaped appointments, research priorities, publication opportunities and international contacts. In historical research this meant moving away from prescribed narratives of class struggle, party leadership and teleological progress, while in philosophy it meant re-entering debates from which Czech thought had been partly excluded after the repression of the post-1968 period. In philology and literary studies, the transformation involved a revaluation of authors, genres, editions and interpretative models that had been pushed to the margins or forced into ideologically acceptable forms. The change was not instantaneous, because the inherited Academy consisted of real workplaces, real collections, real editorial projects and real scholars whose work could not be divided simply into "old" and "new". Some researchers had adjusted to ideological conditions; some had resisted quietly through exact scholarship; some had been excluded; and some had entered the field only after the collapse of communist power. The Academy therefore had to avoid two opposite dangers: the mechanical destruction of inherited structures and the complacent continuation of compromised habits. Its humanities institutes became laboratories of selective continuity, where the question was not

whether to preserve or abolish the past, but how to distinguish scholarly value from ideological deformation (*Institute of History of the CAS, n.d.*; *Kopeček & Kolář, 2007*).

The position of history was especially sensitive because modern Czech and Czechoslovak history had been one of the principal symbolic battlegrounds of the socialist state. The communist regime had not simply censored historical writing; it had organised a public memory in which selected events, personalities and social forces were integrated into an official story of national and social liberation. The post-1989 moment therefore generated a powerful demand for "blank spaces" to be filled: the First Republic, the Protectorate, the Holocaust, the expulsion of the German population, Stalinism, the political trials, collectivisation, the Prague Spring, normalisation, dissent and exile all required renewed empirical and interpretative work. Yet this demand for recovery could not automatically produce methodological renewal. As later observers of Czech historiography noted, the sudden freedom to research forbidden topics often initially encouraged the accumulation of facts, documents and testimonies rather than an immediate theoretical revolution (*Kopeček & Kolář, 2007*). This was understandable: a society emerging from censorship first needed reliable knowledge about what had happened. At the same time, the Academy's historians gradually had to move beyond correction and denunciation towards comparative, social, cultural and transnational approaches.

The Institute of History entered the new period with a strong consciousness of injury and continuity. Its earlier development had been marked by the forced restructuring that followed the Prague Spring, when the institute was renamed and many leading historians were removed, marginalised or otherwise punished. The return of democratic conditions after 1989 therefore meant more than a change of title or administrative status; it meant the restoration of scholarly legitimacy to a discipline that had been damaged by political intervention. The leadership of František Šmahel in the early 1990s symbolised this renewal, because Šmahel represented both high professional authority and the memory of scholars who had suffered from the politics of normalisation. Under the new conditions, the Institute of History strengthened international contacts, revived methodological pluralism, and expanded the infrastructure of historical scholarship through editions, bibliographies, encyclopaedic projects and journals (*Institute of History of the CAS, n.d.*). These activities were not secondary to research but formed the very material basis of a renewed historical profession. In a country where archives and historical publications had long been politically filtered, the reconstruction of such infrastructure was itself an act of intellectual emancipation.

The founding of the Institute of Contemporary History in 1990 was one of the clearest signs that the humanities after 1989 were expected to respond directly to the moral and political needs of society. The institute emerged from the post-November conviction that the period from 1938 to 1989 could no longer remain under the shadow of ideological control, selective memory and censorship. Its creation corresponded to a broader European pattern: democratic societies needed specialised institutions capable of studying dictatorship, war, occupation, collaboration, resistance, repression and social transformation with professional distance. Yet in the Czech case the institute also had an immediate civic dimension, because recent history was not a remote academic subject but a living field of personal memories, family traumas, political disputes and institutional responsibilities. The early leadership of Vilém Prečan, with his experience of exile and documentary work, connected domestic renewal with the transnational circulation of sources, methods and contacts (*Institute of Contemporary History of the CAS, n.d.*). From the beginning, the institute's mission stood at the intersection of

archival research, public debate and democratic self-understanding. This made it one of the most visible examples of how the Academy's humanities were rebuilt not only to study the past but to help society regain a truthful relationship with it.

Philosophy underwent a different but equally significant transformation. The Institute of Philosophy of the Czech Academy of Sciences was re-established in 1990 as a restoration of the original institute founded in the Czechoslovak Academy of Sciences in 1953 and dissolved in 1970 for political reasons (*Institute of Philosophy of the CAS, n.d.*). This institutional fact carried strong symbolic weight, because philosophy had been among the fields most directly affected by ideological surveillance after the defeat of the Prague Spring. Marxist-Leninist orthodoxy had attempted to define the legitimate boundaries of philosophical inquiry, while important currents of Czech philosophy, including phenomenology, personalist thought, religious philosophy, analytical tendencies and independent reflections on history and politics, were restricted or displaced into samizdat, exile or private seminars. After 1989, the re-established institute had to restore philosophy as a plural intellectual discipline rather than as a doctrinal service of the state. This meant reconnecting Czech philosophical research with classical studies, medieval thought, Comeniology, philosophy of science, intellectual history and global philosophical debates. It also meant reinterpreting the legacy of figures such as Jan Patočka, whose philosophical and civic significance became newly visible in the democratic public sphere (*Patočka, 1996*; *Institute of Philosophy of the CAS, n.d.*).

The renewal of philosophy was not only a matter of returning prohibited names to reading lists. It required a transformation of the conditions under which philosophical authority was produced. Under state socialism, official philosophy often derived its institutional security from ideological conformity, while unofficial philosophy derived moral prestige from exclusion and risk. After 1989, these two economies of recognition could no longer function in the same way. Philosophers had to publish internationally, teach, participate in grant competitions, organise conferences and enter debates that were no longer defined primarily by the polarity of regime and dissent. This produced new opportunities but also new tensions. Some forms of dissident authority did not automatically translate into the routines of professional academic philosophy, while younger researchers increasingly measured themselves against international standards, peer review and specialised scholarship. The Institute of Philosophy thus became a site where moral memory, national intellectual tradition and professional internationalisation had to be held together without allowing any one of them to dominate completely.

Philological research after 1989 followed a slower and more cumulative rhythm, because much of its strength lay in long-term projects that could not be remade through political declaration. The study of language, texts and literary history had preserved a degree of scholarly continuity even under restrictive conditions, especially where exact editorial, lexicographical or historical-philological work could be defended as specialised expertise. Yet philology was also deeply connected to cultural identity, and in the Czech context language and literature had long functioned as foundations of national self-understanding. After the Velvet Revolution, this older national role did not disappear, but it had to be reinterpreted in a democratic and European framework. The Czech language was no longer to be treated as a symbolic possession guarded against ideological or foreign threats, but as a living historical and social phenomenon requiring empirical, comparative and public-facing research. Likewise, literary studies could no longer be limited by politically approved canons, but had to recover exile literature, samizdat, religious writing, suppressed modernism, minority voices

and forms of cultural transfer. The rebuilding of philology therefore combined the restoration of continuity with a widening of the cultural archive.

The Czech Language Institute represented one of the clearest examples of long institutional continuity across very different political regimes. Its roots reached back to the lexicographical work of the Czech Academy of Sciences and Arts, especially the effort to prepare a major explanatory dictionary of the national language. After the Second World War, the former dictionary office was transformed into a research institute with wider tasks in dialectology, language history and contemporary standard Czech. After the creation of the Czechoslovak Academy of Sciences, it became one of the anchor institutes of the new academic system, and after 1992 it formed part of the Czech Academy of Sciences as the Czech successor institution (*Czech Language Institute, n.d.*). The post-1989 return of František Daneš to the directorship had particular significance because it connected the democratic renewal with the high tradition of Czech linguistic scholarship. Linguistic research after 1989 did not need to be "liberated" in the same dramatic way as contemporary history, but it did need to redefine its public role in a society moving from ideological uniformity to plural communication. Questions of standard language, language cultivation, dictionaries, dialects, public usage and linguistic advice acquired new significance in a democratic media environment.

The Institute of Czech Literature also stood at the crossroads of continuity and reinterpretation. Founded in the post-war period and incorporated into the Czechoslovak Academy of Sciences in 1953, it had undergone its own institutional changes during the socialist decades, including the transformation into the Institute for Czech and World Literature in 1970 (*Institute of Czech Literature of the CAS, n.d.*). After 1989, literary scholarship had to address a canon that had been distorted by censorship, ideological selection and the separation of official, samizdat and exile cultures. This required not simply the addition of forbidden authors to existing narratives, but a more fundamental reconsideration of how Czech literature had developed under conditions of discontinuity, exile, multilingual contact and political pressure. Scholars had to reconstruct publication histories, textual variants, reception contexts and networks of writers who had lived between official institutions and unofficial circulation. The Academy's literary researchers therefore became custodians of a fractured cultural memory. Their work helped to reconnect Czech literature with the complexity of 20th-century experience, including modernism, Catholic literature, Jewish cultural memory, underground writing, exile publishing and dissident intellectual life.

One of the most important features of the post-1989 humanities was the rehabilitation of scholarly infrastructure. In the natural sciences, infrastructure often means laboratories, instruments and experimental facilities; in the humanities, it often means archives, catalogues, dictionaries, bibliographies, critical editions, source series, scholarly journals and specialised libraries. These forms of infrastructure are less spectacular than machines or laboratories, but they are indispensable for disciplined knowledge. After decades of restricted access, selective publication and disrupted international exchange, the renewal of such infrastructure was a major condition of intellectual freedom. The Institute of History's emphasis on bibliographies, encyclopaedic work and source editions, the Czech Language Institute's lexicographical and advisory functions, the Institute of Czech Literature's textual and documentary work, and the Institute of Contemporary History's publication series all belonged to this broader reconstruction (*Institute of History of the CAS, n.d.*; *Czech Language Institute, n.d.*; *Institute of Contemporary History of the CAS, n.d.*). In this sense, rebuilding the

humanities was not only a matter of changing interpretations. It was also the patient rebuilding of the tools through which future interpretations would become possible.

The Academy's humanities after 1989 also had to renegotiate their relationship with universities. Under state socialism, the Academy had often functioned as a centralised research sector distinct from university teaching, although individual scholars participated in education in various ways. After the transition, this separation became less rigid. Doctoral education, joint projects, teaching, supervision and cooperation with faculties became increasingly important, especially as younger scholars entered research careers under new conditions. The CAS itself later emphasised the participation of Academy researchers in doctoral study programmes and university teaching as part of its mission (*Academy of Sciences of the Czech Republic, n.d.*). For the humanities, this relationship was particularly important because fields such as history, philosophy, philology and literary studies depend heavily on the formation of interpretative communities across generations. The Academy offered research continuity, editorial infrastructure and specialised projects, while universities provided student communities, teaching environments and broader disciplinary reproduction. The post-1989 system therefore required not only institutional reform inside the Academy but a rebalancing of the whole Czech scholarly ecosystem.

Internationalisation was another key dimension of rebuilding. Before 1989, international contacts had existed, but they were uneven, politically filtered and often limited by travel restrictions, ideological suspicion and the division between official and unofficial scholarly networks. After the Velvet Revolution, Czech humanities scholars entered European and global debates with a mixture of enthusiasm, backlog and asymmetry. They needed to translate Czech topics into internationally intelligible questions, but also to resist the danger of becoming merely a regional case study for Western theoretical frameworks. Historical research on communism, nationalism, memory, dictatorship, exile and transformation attracted international attention, while philosophy reconnected with European traditions and philology participated in comparative, Slavic, textual and digital projects. The Institute of Contemporary History, for example, quickly developed international cooperation and acquired a reputation in modern and contemporary history (*Institute of Contemporary History of the CAS, n.d.*). Yet internationalisation was not simply a technical achievement. It forced Czech scholars to ask how national scholarly traditions could remain meaningful within a wider European space without retreating into provincialism.

The post-1989 transformation also changed the status of archives. Archival access was one of the most visible forms of intellectual liberation, especially for historians of the 20th century. Files that had been inaccessible, selectively used or ideologically interpreted could now become the basis for new research into state security, party rule, political repression, cultural policy, exile, religious life and everyday socialism. However, archival freedom brought its own methodological problems. Documents produced by authoritarian institutions could not simply be treated as transparent truth; they had to be read critically as records shaped by surveillance, bureaucratic categories, fear, self-protection and institutional interests. The humanities therefore had to combine the excitement of access with renewed source criticism. This was especially important in contemporary history, where archival discoveries often entered public debate before being fully contextualised. The Academy's role was to slow down the rush from document to judgement by insisting on method, comparison and historical interpretation.

Rebuilding the humanities also meant rethinking the relationship between scholarship and national identity. Czech historical and philological research had long been connected with the formation and preservation of national culture, from the learned societies of the 18th and 19th centuries to the Academy institutions of the 20th century. After 1989, this mission could not simply be abandoned, because language, literature, history and philosophy remained essential to cultural self-understanding. Yet the older national mission had to be freed from both romantic idealisation and socialist instrumentalisation. The democratic humanities had to show that national culture was not a closed essence but a historically changing field shaped by conflict, plurality, translation, migration, religious diversity, social hierarchy and international exchange. This was particularly important in the Czech lands, where German, Jewish, Slovak, Austrian, Central European and broader European contexts were inseparable from Czech history and culture (*Agnew, 2004*; *Sayer, 1998*). The Academy's humanities institutes could therefore serve national culture best not by simplifying it, but by making its complexity visible.

The reassessment of academic elites formed another layer of transformation. The fall of the regime raised difficult questions about responsibility, collaboration, exclusion and rehabilitation. Some scholars had been removed from institutions after 1968 and could now return or be publicly recognised; others had built careers within official structures and had to adapt to a new moral and professional environment. Lustration, generational replacement and institutional elections changed the personnel structure, but they could not resolve every ambiguity of scholarly life under dictatorship. In the humanities, these questions were especially sharp because the disciplines themselves dealt with truth, interpretation, memory and public meaning. The credibility of historians, philosophers and literary scholars depended not only on technical competence but also on the perceived integrity of their relationship to the past. The Academy's post-1989 renewal therefore involved an implicit ethical re-foundation. It had to show that scholarly authority would henceforth be based on evidence, argument, professional evaluation and openness rather than on political loyalty.

The transformation did not remove all structural problems. Funding cuts, competition for grants, uncertainty over institutional futures and the changing legal status of research organisations affected the humanities as much as other fields. The Academy as a whole had to adapt to new conditions of evaluation, international review and diversified financing. Later, the transformation of Academy institutes into public research institutions under the framework of Act No. 341/2005 gave them a clearer legal form, while also placing them in a modern regime of accountability, governance and public reporting (*Act No. 341/2005 Coll., 2005*). For humanities institutes, this meant that traditional long-term scholarship had to coexist with project-based funding and measurable outputs. The tension was obvious: critical editions, dictionaries, archives and bibliographies often require decades, while evaluation systems tend to reward shorter cycles of publication and international visibility. The post-socialist humanities thus had to defend the value of slow scholarship in a system increasingly shaped by competitive research management.

At the same time, the humanities gained new public importance because Czech society was engaged in an intense reinterpretation of its 20th century. Questions of guilt, victimhood, resistance, collaboration, national continuity and European belonging became part of political and media discourse. Historians were invited to comment on anniversaries, archival revelations, property restitution, memory laws, school curricula and public monuments. Philosophers contributed to debates on democracy, responsibility, civil society, Europe and

the moral meaning of dissent. Linguists addressed questions of public language, standard usage, media communication and education. Literary scholars helped restore suppressed authors and interpret cultural forms that had circulated outside official channels. The Academy's humanities therefore did not retreat into the archive after 1989. They became part of a broader democratic conversation, even when they had to resist simplification, politicisation or moral impatience.

The rebuilding of historical research also involved a change in temporal perspective. During the first post-1989 years, attention naturally concentrated on the recent past, especially the communist period and its immediate traumas. Gradually, however, Czech historiography expanded its questions. Medieval, early modern and 19th-century studies were also affected by the transformation, not because they had been equally censored, but because the interpretative frameworks surrounding nation, statehood, religion, social hierarchy and Central Europe changed. František Šmahel's own authority as a medievalist illustrates that the renewal of historical scholarship was not limited to contemporary history. Older periods could now be studied with stronger international integration, comparative methods and less pressure to fit national teleologies. Historical geography, biographical dictionaries, encyclopaedic projects and source editions acquired renewed importance as foundations for broad cultural history (*Institute of History of the CAS, n.d.*). The result was a more plural historical field, in which the recent past remained urgent but no longer monopolised the discipline.

The transformation of philosophy similarly connected older traditions with new questions. Czech philosophy after 1989 could return to the intellectual legacies of Comenius, Masaryk, Patočka and other figures without forcing them into ideological frameworks. Yet it also had to participate in contemporary debates on science, ethics, politics, globalisation and European identity. The Institute of Philosophy's broad structure, including classical and medieval studies, Comeniology, philosophy of science, modern intellectual history and global studies, reflected this pluralisation (*Institute of Philosophy of the CAS, n.d.*). The restoration of philosophical plurality was important not only for specialists but for public culture. A society emerging from ideological monopoly needed habits of argument, conceptual distinction and critical reflection. Philosophy could not dictate political answers, but it could help restore the intellectual conditions under which democratic disagreement becomes meaningful rather than destructive.

In philology, the post-1989 period encouraged a renewed awareness of texts as historical witnesses. Literary works, dictionaries, editions, correspondence, journals and linguistic corpora became evidence of cultural life under pressure. The division between official and unofficial literature had to be reconstructed through bibliographical work, textual scholarship and archival recovery. Exile publications, samizdat editions and underground cultural activity challenged the older idea of literature as a single national canon. At the same time, philologists had to avoid replacing one simplified canon with another heroic narrative of suppression and resistance. Czech literature under socialism included compromise, adaptation, irony, coded speech, aesthetic experiment and ordinary professional work. The Academy's literary and linguistic institutes were well placed to handle this complexity because they possessed the documentary patience required for long-term cultural reconstruction. Their contribution lay not only in judgement but in making the full textual record available for interpretation.

The role of Brno and other non-Prague centres should also be noted. Although Prague remained the dominant institutional centre of the Academy's humanities, Czech scholarly life was never

reducible to the capital alone. The Czech Language Institute's Brno branch, the Brno branch of the Institute of Contemporary History and broader Moravian scholarly networks contributed to the territorial diversification of research. This mattered for historical, linguistic and cultural studies because regional archives, dialects, literary traditions and local memories are not peripheral ornaments but essential parts of national and Central European history. After 1989, the recovery of local and regional perspectives became one way of correcting centralised narratives. It also helped connect professional scholarship with communities outside the main metropolitan institutions. The rebuilding of the humanities was therefore not only a vertical process of reform from Academy leadership to institutes. It was also a horizontal expansion of voices, archives and places.

The digital turn, although more visible in later decades, had roots in the post-1989 reconstruction of scholarly infrastructure. Bibliographies, catalogues, dictionaries, source databases and textual corpora gradually moved from printed or internal forms into electronic environments. This development changed the humanities by expanding access, accelerating search, enabling new types of linguistic and literary analysis, and strengthening cooperation between institutes. The Czech Language Institute's lexicographical tradition, the Institute of History's bibliographical work and the documentary practices of literary and contemporary historical research all provided fertile ground for digital humanities. Digitalisation did not replace classical philological and historical skills; rather, it made their disciplined procedures newly scalable. In the Czech case, this was especially important because so much post-1989 work involved recovering dispersed, censored or fragmented materials. The digital humanities thus continued the older Academy mission of preserving and organising knowledge, but under technological conditions that made wider public and international access possible.

The humanities after ideology were therefore not "post-ideological" in a naïve sense. They did not enter a neutral world free from political assumptions, social pressures or cultural conflicts. Instead, they moved from a system of explicit ideological monopoly to a plural public sphere in which memory, identity, European integration and social transformation remained contested. This required new forms of scholarly self-discipline. Historians had to resist both nostalgia and prosecutorial simplification; philosophers had to avoid turning dissident moral capital into unquestioned authority; philologists had to rebuild canons without reducing literature to political testimony. The Academy's institutional setting offered a relatively stable environment for this work, because it supported long-term projects that could outlast immediate political fashion. At its best, the Academy's humanities helped Czech society replace imposed certainty with argued complexity.

This reconstruction also changed the symbolic meaning of the Academy itself. Under the Czechoslovak socialist model, the Academy had been a centralised institution closely tied to the state's vision of planned science. After 1989 and especially after the establishment of the Czech Academy of Sciences as the successor to the former Czechoslovak Academy, the institution had to redefine itself as a public, autonomous and internationally oriented research body (*Academy of Sciences of the Czech Republic, n.d.*). In the humanities, this redefinition was particularly visible because the disciplines dealt directly with national memory, language, culture and civic self-interpretation. The Academy could no longer claim authority through proximity to the state. It had to earn authority through scholarly quality, openness, public usefulness and institutional self-government. The rebuilding of historical, philosophical and philological research was therefore also a rebuilding of the Academy's moral profile.

The post-1989 humanities were marked by a productive tension between recovery and innovation. Recovery was necessary because names, texts, archives, topics and methods had been suppressed or distorted. Innovation was necessary because democratic scholarship could not be satisfied with merely reversing ideological signs. The most successful institutions and research programmes were those that combined archival seriousness with methodological openness, national responsibility with international comparison, and public engagement with scholarly restraint. The Academy's historians, philosophers and philologists had to learn to speak simultaneously to Czech society, to specialised international communities and to their disciplinary traditions. This triple audience made their work demanding, but also gave it unusual richness. The humanities became one of the places where the Czech Republic could examine not only what had happened to it, but how it wished to understand itself after the end of ideological rule.

Thus, the rebuilding of historical, philosophical and philological research after 1989 was a central chapter in the transformation of the Czech Academy of Sciences. It restored suppressed institutions, opened forbidden questions, renewed scholarly infrastructure, reconnected Czech research with international debates and redefined the public mission of the humanities. The process was neither simple nor purely celebratory, because it involved difficult judgements about continuity, compromise, exclusion, rehabilitation and methodological delay. Yet its broader significance is clear: the Academy's humanities helped transform freedom from a political event into a sustained scholarly practice. They showed that democracy requires not only elections and institutions, but also archives, dictionaries, editions, critical concepts, historical patience and a disciplined language for speaking about the past. In this sense, the humanities after 1989 became one of the essential foundations of the modern Czech Academy's identity.

2. Archival Freedom and New Historiographical Questions

The opening of archives after 1989 was one of the most decisive conditions for the renewal of Czech and Czechoslovak historiography. Political freedom by itself could not automatically produce historical knowledge, because historical knowledge depends on sources, access, institutional trust and the ability to compare documentary evidence with memory, testimony and inherited interpretation. Under state socialism, archives had not been completely closed, but access was selective, supervised and uneven, especially for topics touching upon the Communist Party, the security apparatus, the post-war settlement, the Prague Spring, normalisation, exile and dissent. The collapse of the regime therefore changed not only the political atmosphere around history but the practical foundations of historical work. Researchers could begin to ask questions that had previously been forbidden, discouraged or artificially narrowed by the archive itself. Yet archival freedom was never a simple passage from darkness to light. It created a new terrain in which historians had to learn how to use liberated documents without turning them into political weapons or treating them as self-explanatory truth (*Kopeček & Kolář, 2007*; *Institute of Contemporary History of the CAS, n.d.*).

The first post-November years were marked by the powerful social expectation that archives would reveal the truth about the recent past. This expectation was understandable, because official historical narratives had been saturated with silences, euphemisms and ideological mythologies. Families wanted to know what had happened to persecuted relatives; former dissidents wanted to understand the mechanisms of surveillance; citizens wanted to see the

structure of collaboration and coercion; politicians wanted legal and moral criteria for excluding the agents of the old regime from sensitive offices. Historians, however, faced a more complex task than simply “opening files”. They had to reconstruct provenance, institutional context, authorship, bureaucratic language and the purposes for which documents had been produced. Secret police reports, party records and personnel files were not neutral mirrors of reality; they were products of power, suspicion and administrative self-preservation. The new archival freedom therefore required not less source criticism than before, but more of it.

The founding of the Institute of Contemporary History in 1990 was closely connected with this new archival situation. The institute was established in the post-November atmosphere to provide independent research into Czechoslovak history between 1938 and 1989, precisely the period most heavily affected by ideological supervision and censorship under communist rule (*Institute of Contemporary History of the CAS, n.d.*). Its emergence reflected a broad conviction that democratic Czechoslovakia needed professional historical inquiry into the Nazi occupation, the post-war settlement, Stalinism, the reform communist movement, the Prague Spring, normalisation and the final crisis of the regime. The institute’s mission did not merely consist of studying recent history as another chronological period. It was expected to help restore society’s capacity to think historically about events still present in living memory. This gave contemporary history an unusual public burden. It had to combine scholarly distance with the urgency of a society trying to understand its own moral and political biography.

Archival freedom immediately expanded the range of possible questions. Instead of writing the history of modern Czechoslovakia mainly through official political narratives, historians could study decision-making mechanisms, informal networks, surveillance practices, everyday adaptation, social mobility, economic constraint, cultural censorship and the interior life of institutions. They could examine how the Communist Party functioned not only as an ideological centre but as a bureaucratic organisation with files, committees, careers, rivalries and regional structures. They could explore how the security services produced knowledge about society and how that knowledge shaped repression, intimidation and negotiation. They could ask how ordinary people interacted with the state, not only as victims or collaborators but also as workers, parents, believers, consumers, neighbours and readers. This shift from official narrative to social and institutional analysis was one of the most important methodological consequences of open archives. It allowed Czech historiography to move beyond a purely political chronicle and towards a more layered history of power, society and experience.

The archives also transformed the study of 1968 and normalisation. During the socialist period, the Prague Spring had been either condemned through the language of “counter-revolution” or treated with extreme caution, while normalisation had often appeared in official discourse as a restored order. After 1989, documents from party bodies, state administration, cultural institutions, security organs and personal collections made it possible to reconstruct the reform movement, the Soviet-led invasion, political purges, intellectual resistance and the everyday mechanisms of post-1968 conformity. The Institute of Contemporary History’s early publication series on the Czechoslovak crisis of 1967–1970 signalled the importance of source editions for this task (*Institute of Contemporary History of the CAS, n.d.*). These editions did more than supply material for specialists. They helped establish a new public vocabulary for speaking about a period that had shaped the careers, fears and memories of several generations. Archival publication thus became an instrument of democratic clarification.

The question of the security services became particularly charged. Secret police archives attracted public attention because they seemed to promise direct access to hidden truth: names of informers, files on dissidents, reports on surveillance, operational plans and records of repression. Yet the apparent concreteness of such material could be deceptive. A police file may record an encounter but not its emotional meaning; it may list a collaborator but not explain the conditions of pressure, fear or opportunism; it may contain denunciations, fabrications or bureaucratic exaggerations. Historians had to distinguish between the archive as evidence and the archive as a product of authoritarian imagination. This methodological caution did not relativise repression. Rather, it made the study of repression more accurate by refusing to adopt the categories of the repressing institution uncritically. The opening of security archives therefore created both a new empirical field and a new ethical discipline (*Act No. 181/2007 Coll., 2007*; *Williams, 2003*).

The later creation of the Security Services Archive and the Institute for the Study of Totalitarian Regimes institutionalised a part of this archival and memory agenda outside the Academy, but it also affected Academy-based historical research. The Security Services Archive was established under Act No. 181/2007 Coll., which laid the legal foundation for the Institute for the Study of Totalitarian Regimes and the archive responsible for records of the security apparatus (*Act No. 181/2007 Coll., 2007*). This development demonstrated that archival freedom had become a matter of state policy, public memory and democratic legitimacy, not merely an internal concern of historians. For Academy historians, the existence of such institutions created opportunities for cooperation, comparison and access, but also raised questions about the boundary between scholarly research and official memory politics. The Academy's role was not to monopolise historical interpretation. Its role was to insist that even the morally urgent study of dictatorship required method, context and scholarly independence.

The National Archives and other public archival institutions formed the broader infrastructure within which this transformation took place. Czech archival law and research rules gradually defined the conditions under which researchers could access records, finding aids, copies and research rooms (*Act No. 499/2004 Coll., 2004*; *National Archives, n.d.*). This legal and administrative framework mattered because archival freedom is not only a political slogan; it is a system of permissions, catalogues, professional archivists, preservation procedures, privacy rules and reading-room practices. The democratisation of historical knowledge therefore depended on mundane but essential institutional work. Files had to be arranged, described, conserved, transferred and made intelligible. Without archivists and archival institutions, the opening of the past would have remained rhetorical. The post-1989 transformation of historiography was therefore also a transformation of archival labour.

Within the Czech Academy of Sciences, the Masaryk Institute and Archives became one of the key institutions linking historical research, archival preservation and the history of scholarship. Its archival departments collect and process records of the Academy, the fonds of older scientific institutions and the personal papers of scientists working in the Czech lands (*Masaryk Institute and Archives of the CAS, n.d.*). This role gave the Academy an internal archive of its own institutional memory. It allowed researchers to study not only national political history but also the history of scientific institutions, academic elites, scholarly networks and disciplinary development. Such archives are crucial for an institutional history of the Academy because they reveal how decisions were made, how research priorities changed, how institutes communicated with the state and how scholars experienced political pressure. In

this respect, archival freedom also turned the Academy itself into an object of historical investigation.

The return of the Masaryk tradition after 1989 was inseparable from archival recovery. Tomáš Garrigue Masaryk had been a foundational figure of democratic Czechoslovakia, yet under communist rule his legacy was selectively interpreted, marginalised or ideologically reframed. The reinstatement of the T. G. Masaryk Institute in 1990 and the later development of the Masaryk Institute within the Academy gave institutional form to a broader re-engagement with democratic political thought, presidential culture, the First Republic and Central European liberal traditions (*Masaryk Institute and Archives of the CAS, n.d.*). Archival access made it possible to study Masaryk, Edvard Beneš and their circles not as icons alone but as historical actors embedded in correspondence, institutions, political conflicts and international contexts. This was important because post-1989 society needed more than symbolic rehabilitation. It needed critical knowledge of the democratic traditions to which it claimed to return.

The Institute of History also benefited from the new archival environment, though its chronological scope extended far beyond the 20th century. Its work covers Czech, Czechoslovak and general history from the early Middle Ages to the modern and contemporary periods, while also providing scholarly infrastructure through source editions, journals, bibliographies and specialised libraries (*Institute of History of the CAS, n.d.*). After 1989, the institute's earlier focus on history up to 1945 or 1948 gradually expanded towards communist Czechoslovakia. This shift showed that archival freedom was not restricted to the most recent past but reshaped the entire architecture of historical inquiry. Medievalists, early modernists and 19th-century historians also worked in a different intellectual climate, because older narratives of nationhood, class, statehood and Central Europe could now be reconsidered without ideological constraints. The opening of archives therefore produced a general rebalancing of Czech historiography, even where the sources themselves were not newly available.

One of the most visible new historiographical questions concerned the post-war expulsion and transfer of the German population. Before 1989, this subject was embedded in official narratives of anti-fascist justice and national liberation, while its moral and social complexity was often suppressed. After the opening of archives and the pluralisation of public debate, historians could examine local violence, administrative procedures, property transfers, international diplomacy, demographic transformation and the long-term effects on borderland society. This did not mean replacing one national myth with another. Rather, it meant allowing the topic to be studied as part of a broader Central European history of war, revenge, ethnic cleansing, state-building and memory. Kopeček and Kolář noted that after 1989 the so-called Sudeten German question became one of the most intensely discussed themes in Czech historiography and society (*Kopeček & Kolář, 2007*). Its prominence showed how archival freedom could reopen questions that touched the moral foundations of post-war national identity.

The Holocaust and the history of the Jewish population also acquired new research depth in the post-1989 archival environment. The communist regime had not denied Nazi persecution, but it often subsumed Jewish suffering under broader anti-fascist and class narratives. After 1989, historians could more fully explore the specific experience of Czech and Moravian Jews, the functioning of the Protectorate, the role of local institutions, property confiscation,

restitution, memory and post-war silence. This work required cooperation across archives in the Czech Republic, Germany, Austria, Israel and other countries. It also required sensitivity to the relationship between documentary evidence and survivor testimony. The Academy's contribution to such fields lay in its ability to support long-term scholarly work that connected national archives with international research networks. The opening of archives thus helped Czech historiography enter broader European debates about genocide, collaboration, restitution and memory.

The history of exile became another major field transformed by access to sources. Czech and Czechoslovak exile communities had preserved documents, periodicals, correspondence and institutional records that were either inaccessible or ideologically discredited before 1989. After the transition, these materials could be reintegrated into national history. Exile was no longer treated merely as a political deviation or foreign influence but as part of the intellectual, cultural and scientific life of Czechoslovakia. Figures who had worked abroad as historians, philosophers, journalists, scientists or cultural mediators could be studied in relation to domestic developments. The return of exile documentation also complicated the idea of a single national scholarly space. It showed that Czech culture and science had continued across borders, languages and institutions even when domestic public life was constrained.

Archival freedom also reshaped the history of dissent. Before 1989, dissent was criminalised, ridiculed or erased from official narratives; after 1989, it risked being idealised as the pure moral centre of the nation. Archives allowed historians to move beyond both denunciation and sanctification. They made it possible to study Charter 77, samizdat, underground culture, religious networks, ecological activism, independent seminars and human rights initiatives as social, intellectual and communicative phenomena. Researchers could examine not only public declarations but also networks of friendship, surveillance, fear, disagreement and international support. This helped transform dissent from a heroic legend into a historical field. Such transformation did not diminish its moral importance. It made that importance more historically intelligible.

The new archival situation also gave historians access to the internal world of socialist institutions. Schools, factories, editorial offices, theatres, research institutes, party committees, trade unions and local administrations all produced records that could be used to study the everyday operation of the regime. This broadened the historiography of communism beyond the history of repression alone. Historians could ask how authority was negotiated, how people adapted to rules, how shortages shaped social relations, how cultural institutions managed censorship, how experts interacted with party officials and how late socialism created forms of private retreat and public conformity. This development corresponded to broader international shifts in the study of socialist societies, where the focus moved from totalitarian control alone to practices of everyday life, consumption, gender, expertise and social negotiation (*Bren, 2010*; *Kopeček & Kolář, 2007*). Open archives made such questions empirically possible in the Czech case.

The archival turn also affected the history of science and the Academy itself. The Czechoslovak Academy of Sciences had been both a research institution and part of the socialist state's planned scientific system. Its archives therefore contain evidence of scientific ambition, international exchange, ideological pressure, personnel decisions, disciplinary restructuring and cooperation with industry and government. After 1989, historians could investigate how scientific autonomy had been restricted, negotiated or preserved under different political

conditions. They could examine purges after 1968, the fate of excluded scholars, the position of institutes during normalisation and the transformation of research priorities after the Velvet Revolution. This was essential for the Academy's self-understanding, because institutional memory cannot be reduced to anniversary celebration. It must include the uncomfortable history of dependence, adaptation and rupture.

The opening of archives also changed the relationship between professional historians and the wider public. Archival discoveries entered newspapers, television, museums, court cases, school textbooks and political debates. This expanded the social importance of historical expertise but also exposed historians to pressure for immediate judgement. Public debate often wanted names, guilt and clear moral categories, while scholarship required context, comparison and caution. The Academy's historians were therefore placed in a difficult position. They could not withdraw from public discussion, because the past was being actively used in democratic reconstruction. Yet they also had to protect historical interpretation from becoming a mere extension of political conflict. Archival freedom thus intensified the public responsibility of the historian.

The problem of lustration illustrates this tension especially clearly. Lustration laws were intended to protect the new democratic state from the influence of former communist functionaries, secret police officers and collaborators in sensitive positions (*David, 2003*; *Williams, 2003*). Their implementation depended partly on records produced by the former regime itself. This created a paradox: democracy used the documentary remains of dictatorship to define the boundaries of public trust. Historians were not the same as lustration authorities, but their work unfolded in a society where archival files could affect reputations, careers and political legitimacy. This made methodological precision and ethical restraint even more important. The file had to be read not only as evidence but as an artefact of power.

Another new historiographical question concerned the relationship between memory and documentation. After 1989, oral history, memoirs and witness testimony became indispensable, especially for the study of persecution, dissent, exile, imprisonment and everyday life. Yet memories did not always match archival documents, and documents did not always capture the subjective experience of historical actors. The best post-1989 historiography did not choose simply between archive and memory. It treated their tension as productive. Archival records could challenge self-justifying memories, while testimony could expose the blind spots and violence of bureaucratic documentation. In this way, archival freedom strengthened rather than weakened the need for plural sources.

The generational dimension of archival freedom was also significant. Older scholars who had experienced exclusion after 1968 often returned to archives with biographical urgency, while younger historians trained after 1989 approached the same materials with different theoretical questions and fewer personal memories. This generational shift was visible in the Institute of Contemporary History, where the founding generation gradually gave way to researchers formed under democratic conditions (*Institute of Contemporary History of the CAS, n.d.*). The change did not necessarily produce a simple opposition between memory and method. Rather, it created a layered discipline in which lived experience, documentary recovery and international methodological training interacted. The maturing of Czech historiography after 1989 depended on this dialogue between generations. Without it, the field might have remained either commemorative or prematurely detached.

International comparison became increasingly important as Czech historians gained access to sources and networks. The history of communism, dictatorship, resistance and transition could now be studied alongside the histories of Poland, Hungary, East Germany, Slovakia and the Soviet Union. Archival openness allowed Czech scholars to participate in broader debates about state socialism, post-war violence, memory politics, transitional justice and Europeanisation. At the same time, Czech archives offered foreign scholars rich material for comparative research. The Institute of Contemporary History's cooperation with international institutions and its projects on socially relevant topics demonstrate this outward turn (*Institute of Contemporary History of the CAS, n.d.*). The result was a historiography less confined to national self-explanation and more capable of seeing Czech experience as part of European history.

The expansion of archival access also encouraged new forms of historical infrastructure. Bibliographies, databases, digital catalogues, thematic portals and source editions became essential tools for a profession dealing with large quantities of newly available material. The Institute of History's continuous bibliography and source edition projects, the Institute of Contemporary History's documentation collections and the Masaryk Institute and Archives' databases all contributed to this infrastructure (*Institute of History of the CAS, n.d.*; *Masaryk Institute and Archives of the CAS, n.d.*). These tools did not merely support research after the fact. They shaped the questions that could be asked, the connections that could be seen and the audiences that could access historical knowledge. In the digital age, archival freedom increasingly meant not only physical access to documents but also the intelligent organisation of information.

However, the opening of archives did not eliminate silences. Some records had been destroyed, manipulated, dispersed or never created. Others remained restricted because of privacy, state security, copyright or preservation concerns. In addition, archives often preserve the perspective of institutions more fully than the perspective of those who lived under them. The poor, the marginalised, the Roma, women in informal labour, religious minorities, migrants and ordinary citizens may appear only fragmentarily or through the language of administration. Contemporary Czech historiography therefore had to ask not only what the newly opened archives revealed but what they still concealed. Archival freedom was a beginning, not a guarantee of completeness.

This awareness helped generate new questions about marginalised groups and everyday experience. The Institute of Contemporary History's current research themes include democracy, everyday life in dictatorships, the Roma and other marginalised groups, social transformations and the history of thought and science (*Institute of Contemporary History of the CAS, n.d.*). Such topics reflect a historiographical movement away from a narrow focus on political elites and towards a broader analysis of society. Open archives made this possible, but they did not make it automatic. Historians had to combine state records with local archives, oral testimony, visual sources, material culture, press collections and private papers. The more democratic the questions became, the more diverse the source base had to be.

The political sensitivity of archival research also affected the public image of the Academy. The Czech Academy of Sciences defines its mission as research across the natural, technical and social sciences and the humanities, taking into account the needs of Czech society and national culture (*Academy of Sciences of the Czech Republic, n.d.*). In the field of history, this

mission acquired a particular meaning after 1989. The Academy was expected to contribute to society's understanding of the past, but it also had to protect the autonomy of scholarship from immediate ideological demands. Its authority therefore rested not on producing a new official history, but on sustaining the conditions for critical historical inquiry. The distinction is crucial. Democratic society does not need the Academy to replace one authorised narrative with another; it needs the Academy to keep historical knowledge open, verifiable and intellectually responsible.

Archival freedom also altered the emotional economy of historical work. Historians were not dealing only with distant documents but with records that could wound, shame, rehabilitate or unsettle living people. Files on collaboration, surveillance, denunciation, persecution and property confiscation entered family histories and public reputations. This made empathy and caution part of scholarly professionalism. A historian of dictatorship cannot read documents as if they were neutral administrative traces alone. They contain human fear, coercion, self-protection and sometimes deliberate cruelty. The archives after 1989 therefore taught Czech historiography that truth is not only a matter of discovery. It is also a matter of responsible interpretation.

In the longer perspective, the opening of archives transformed the rhythm of Czech historical scholarship. The first phase after 1989 was often dominated by recovery, publication and correction. Later phases increasingly involved synthesis, comparison, theoretical reflection and public history. This sequence is understandable: before historians could write new interpretations, they needed to know what the sources contained. Yet the best work did not stop at documentary accumulation. It asked how regimes functioned, how societies remembered, how identities changed and how democracy inherited the structures of dictatorship. Archival freedom thus did not merely add new facts to old narratives. It made possible a new historiographical architecture.

Thus, archival freedom after 1989 became one of the foundations of the modern Czech humanities. It opened sources, created new research institutions, redefined contemporary history, transformed the study of dictatorship and democracy, and made the Academy itself available for critical institutional history. At the same time, it forced historians to confront difficult methodological and ethical questions: how to read documents produced by power, how to connect archives with memory, how to serve public debate without surrendering to political simplification, and how to recognise the silences that remain even in open collections. The significance of this transformation lies not only in the quantity of newly accessible material. It lies in the emergence of a democratic historical culture in which archives, criticism and public responsibility became inseparable.

3. The Academy as Guardian of Cultural and Scholarly Memory

The Czech Academy of Sciences has never been only a research organisation in the narrow administrative sense of the term. In the humanities, and especially after 1989, it also became a custodian of cultural memory, scholarly continuity and the documentary traces of Czech intellectual life. This role was not invented by the democratic transformation, because the Academy inherited older traditions from learned societies, national scholarly institutions, archival collections, editorial projects and lexicographical enterprises. Yet the meaning of guardianship changed profoundly after the collapse of ideological rule. Under socialism,

memory had often been organised, censored or selectively interpreted by the state; after the Velvet Revolution, the Academy had to help transform memory into an open field of research, debate and public access. The task was not simply to preserve the past, but to preserve it in ways that allowed society to ask new questions. In this respect, the Academy's humanities institutes stood at the intersection of scholarship, national culture and democratic responsibility (Academy of Sciences of the Czech Republic, n.d.; Franc & Mádlová, 2014).

The phrase "guardian of memory" may sound ceremonial, but in the context of the Czech humanities it has a very concrete institutional meaning. Memory is guarded through archives, libraries, dictionaries, bibliographies, critical editions, databases, corpora, expert advisory services, personal fonds, scholarly journals and long-term research projects. These instruments are less visible than political speeches or public monuments, yet they determine what can be known, checked, cited and transmitted. Without them, cultural memory becomes dependent on anecdote, nostalgia, ideological simplification or market visibility. The Academy's particular strength has been its ability to maintain slow, cumulative and technically demanding forms of scholarship that do not always fit short-term political or commercial expectations. This is especially important for small and medium-sized national cultures, where the survival of scholarly infrastructure cannot be left entirely to universities, publishing houses or private foundations. The Czech Academy therefore performs a memory function not by replacing society's plural voices, but by sustaining the tools through which those voices can be studied responsibly.

The transformation after 1989 intensified this memory function because Czech society was confronted with several pasts at once. There was the democratic memory of the First Republic, long distorted by communist interpretation; the traumatic memory of the Protectorate and the Holocaust; the contested memory of post-war violence and the expulsion of the German population; the memory of Stalinism, political trials and collectivisation; the reform memory of 1968; the bitter memory of normalisation; and the newly celebrated but also complex memory of dissent and exile. These layers did not form a harmonious national narrative. They often contradicted one another, divided families, shaped political identities and raised moral questions that could not be answered by commemoration alone. The Academy's historians, literary scholars, philosophers and linguists contributed by slowing down the movement from memory to judgement. Their work insisted that public remembrance should be accompanied by documentation, source criticism, linguistic precision and historical context (Kopeček & Kolář, 2007; Suk, 2003).

The Masaryk Institute and Archives of the Czech Academy of Sciences is one of the clearest institutional embodiments of this guardianship. Its archival division collects and processes records of the Academy, archival collections of earlier scientific institutions and personal papers of scholars who worked in the Czech lands. This means that the Academy preserves not only external national history but also its own scientific biography. The fonds of the Czechoslovak Academy of Sciences and the Czech Academy of Sciences make it possible to study the continuity and discontinuity of institutes, departments, research programmes and academic elites from the socialist period into the democratic era. Such archival work is indispensable for an institutional history of science, because it allows scholars to reconstruct how scientific authority was produced, negotiated and sometimes compromised. The archive therefore protects the Academy from becoming a purely celebratory institution of anniversaries. It enables a more demanding form of self-knowledge, one that includes

achievement, pressure, adaptation, exclusion and reform (Masaryk Institute and Archives of the CAS, n.d.; Masaryk Institute and Archives of the CAS, n.d.).

The Masaryk legacy itself occupies a special place in the Academy's work of memory. Tomáš Garrigue Masaryk is not only a political symbol of democratic Czechoslovakia but also a figure through whom Czech intellectual culture connects philosophy, sociology, history, religion, ethics and public life. Under communist rule, his legacy was frequently reframed or marginalised, because it pointed to democratic, liberal and humanistic traditions incompatible with the ideological monopoly of the party-state. After 1989, the renewed institutional study of Masaryk did not merely restore a forbidden national icon. It created an opportunity to examine the intellectual foundations of Czech democracy with scholarly tools rather than patriotic reverence alone. This distinction was crucial. A democratic culture needs symbols, but it also needs institutions capable of studying those symbols critically, historically and philologically.

The Academy's role as guardian of memory is also visible in the preservation of the Czech language. The Czech Language Institute inherited a long lexicographical and linguistic tradition reaching back to the older Czech Academy of Sciences and Arts and to the national importance of dictionary-making. Language has been one of the deepest carriers of Czech cultural identity, especially because the national revival itself was inseparable from philology, grammar, vocabulary, literature and education. After 1989, however, the Academy could no longer approach language cultivation as a defensive national project alone. The Czech language had to be studied as a living system exposed to democratisation, market communication, media pluralism, European integration, migration, digital communication and global English. The Language Consulting Centre of the Czech Language Institute illustrates this public dimension, because it offers expert advice on spelling, morphology, meaning, etymology, usage and formulation to Czech language users. Here the Academy guards memory not by freezing language, but by helping speakers understand its structure, history and public norms (Czech Language Institute, n.d.).

This linguistic guardianship is particularly important because language memory is often invisible to its speakers. Every dictionary entry, dialect record, etymological explanation, corpus annotation and normative recommendation preserves traces of earlier usage and helps society negotiate change without losing continuity. Czech, like all national languages, is not a museum object; it changes through schools, media, bureaucracy, literature, technology and everyday speech. Yet change becomes culturally intelligible only when there are institutions capable of describing it. The Academy's linguistic work therefore joins descriptive science with public service. It gives citizens, teachers, journalists, editors, courts, offices and publishers access to expert knowledge that is not merely a matter of personal taste. In this way, the Academy protects the linguistic foundations of public communication, which are themselves a crucial part of democratic culture.

The Institute of Czech Literature performs a related but distinct memory function. It preserves and studies literary history not as a simple canon of great books, but as a complex ecosystem of authors, journals, publishing houses, genres, editions, criticism, reception, exile, samizdat and popular culture. Its history reflects the larger institutional biography of Czech literary studies: established in the post-war period, incorporated into the Czechoslovak Academy of Sciences, transformed during normalisation, and renamed after 1993 in connection with a renewed conception of Czech studies. After 1989, its task was not only to add prohibited

writers back into a textbook narrative. It had to reconstruct the fractured literary field of the 20th century, including authors who had written in exile, published in samizdat, worked under censorship or remained outside dominant cultural institutions. Literary memory in this sense is not passive preservation. It is active reconstruction of a cultural field that political regimes had divided into official, unofficial and foreign circuits (Institute of Czech Literature of the CAS, n.d.; Holy, 1996).

The Academy's literary databases and bibliographies demonstrate how memory is transformed into usable knowledge. The Dictionary of Czech Post-1945 Literature, for example, is a cyclically updated electronic database based on earlier dictionaries that were no longer constrained by pre-November ideological limitations. Its purpose is to provide professionally processed information for experts and the general public alike. The Czech Literary Science bibliographic databases record the reflection of Czech literature and literary studies in periodicals, newspapers, cultural journalism, scholarly press and book publications from 1945 to the present. The Retrospective Bibliography of Czech Literature preserves an even broader documentary world, including materials from Czech and German periodicals in the Czech lands before 1945. These projects reveal the Academy's memory role with unusual clarity: they do not simply interpret literature, but ensure that the documentary conditions for future interpretation remain available (Digital Humanities Czech Academy of Sciences, n.d.; Digital Humanities Czech Academy of Sciences, n.d.; Digital Humanities Czech Academy of Sciences, n.d.).

The significance of such bibliographical and lexicographical projects is easy to underestimate. A bibliography may seem less dramatic than a monograph on dictatorship or a public exhibition on national trauma. Yet bibliographies determine whether a literary work, review, polemic, obituary, translation, exile journal or regional newspaper can be found at all. They transform dispersed traces into a structured cultural archive. In a national culture shaped by censorship, exile, multilingualism and political rupture, this work is especially important. It allows scholars to reconstruct connections that were intentionally broken or accidentally lost. It also democratises memory by allowing users outside narrow academic circles to discover authors, texts and debates that would otherwise remain hidden.

The Library of the Czech Academy of Sciences adds another layer to this system of guardianship. Its Digital Library contains digitised periodicals and monographs produced by the institutes of the Academy and their predecessors. This is not simply a technical service, although the technical side is highly important. Digitisation changes the social life of scholarly memory by making older publications searchable, accessible and less dependent on physical proximity to Prague collections. It also preserves fragile materials and helps integrate Czech academic production into wider digital environments. For the humanities, such digital access is transformative because it allows historians, philologists, literary scholars, sociologists and philosophers to work across large bodies of material. The Academy thus carries older traditions of collecting and publishing into the digital age (Library of the Czech Academy of Sciences, n.d.).

Digital humanities projects do not abolish classical scholarship; they extend it. The Academy's databases of literary figures, bibliographies, correspondence, dictionaries and digitised periodicals are meaningful only because they are built on decades of archival, editorial and philological expertise. The digital format changes speed, scale and access, but the underlying scholarly virtues remain accuracy, provenance, citation, completeness and interpretative

caution. This continuity is important because digital culture can encourage an illusion of immediate knowledge. Searchability does not automatically create understanding. The Academy's role is to ensure that digital memory remains scholarly memory, structured by method rather than by accidental visibility or algorithmic popularity.

The Academy also guards scholarly memory through the history of its own disciplines. Every institute contains not only present research teams but also traces of earlier disciplinary formations, lost departments, reorganised laboratories, dismissed scholars, renamed journals and unfinished projects. In the humanities, this disciplinary memory is especially significant because research traditions are transmitted through editions, methods, terminologies and intellectual genealogies. The Institute of History, the Institute of Philosophy, the Czech Language Institute, the Institute of Czech Literature and the Institute of Contemporary History all carry institutional biographies that reflect broader political changes. Their archives and publications show how disciplines survived monarchy, republic, occupation, Stalinism, reform communism, normalisation and post-socialist transformation. To write the history of these institutes is therefore to write a history of the changing conditions under which Czech society has allowed itself to know its own past.

The memory of excluded and returning scholars was another essential element of the post-1989 Academy. After the purges that followed the Prague Spring, many historians, philosophers, sociologists and literary scholars were dismissed, demoted, silenced or pushed into marginal employment. Others continued their work in exile, samizdat, private seminars or foreign universities. The democratic transformation created space for rehabilitation, but rehabilitation was not only a personnel matter. It required the restoration of interrupted intellectual lineages. Works that had circulated unofficially or abroad had to be republished, cited, taught and integrated into research narratives. The Academy's memory role therefore included the re-inscription of damaged scholarly biographies into the visible history of Czech science.

At the same time, guardianship of scholarly memory required honesty about compromise. Institutions under dictatorship are rarely divided neatly between heroes and servants of power. Many scholars protected valuable work through cautious adaptation; others collaborated more actively with ideological expectations; some resisted openly; many lived in morally ambiguous zones of professional survival. A mature institutional memory cannot be built on amnesia or retrospective purity. The Academy's post-1989 humanities had to develop a language capable of recognising both scholarly achievement and political entanglement. This was particularly important for the Academy itself, because its socialist predecessor had been both a site of genuine research excellence and a component of the planned ideological state. To guard memory meant to preserve evidence for this complexity rather than to simplify it into either condemnation or nostalgia.

The Academy's guardianship also extends to philosophical memory. The Institute of Philosophy, restored after 1989, reconnected Czech scholarship with traditions interrupted by political intervention, including phenomenology, Comeniology, classical studies, medieval thought, philosophy of science and modern intellectual history. The legacy of Jan Patočka, in particular, illustrates the link between philosophical research and civic memory. Patočka's writings and public role in Charter 77 made him a figure through whom Czech philosophy entered the moral history of dissent and European debates about responsibility. Yet the Academy's task was not to turn him into a monument. It was to edit, interpret, contextualise

and discuss his thought as philosophy. This is the difference between cultural memory and scholarly memory: the former remembers a name, while the latter reconstructs arguments, texts, contexts and reception (Patočka, 1996; Institute of Philosophy of the CAS, n.d.).

Historical memory after 1989 was also inseparable from the study of totalitarianism, democracy and public life. The Institute of Contemporary History, founded in 1990, became one of the principal sites for the professional study of the period from 1938 to 1989. Its work helped place recent Czech and Czechoslovak history within broader European questions about dictatorship, war, occupation, repression, exile, dissent and transition. Yet its importance cannot be measured only by publications. It offered society an institutional space in which painful memories could be transformed into research questions. This transformation is essential for democratic culture. A society that remembers only through accusation or sentiment remains vulnerable to political manipulation; a society that can research its own traumas gains a more durable form of freedom (Institute of Contemporary History of the CAS, n.d.; Bren, 2010).

The Academy's memory function is not confined to national history in the narrow sense. Czech culture has always been shaped by Central European entanglements, including German, Austrian, Jewish, Slovak, Polish, Hungarian and wider European contexts. The humanities institutes of the Academy are therefore guardians not of a sealed national narrative but of a complex cultural region. This is visible in research on multilingual literary culture, Bohemian lands history, Jewish memory, the Habsburg monarchy, Czech-German relations, exile networks and European intellectual exchange. The national importance of the Academy lies precisely in its ability to show that national culture is historically plural. It guards Czech memory by resisting the temptation to make it simpler than it was (Agnew, 2004; Sayer, 1998).

This plural understanding of memory also affects the interpretation of cultural heritage. The Academy's humanities do not treat heritage only as a collection of monuments, books and anniversaries. Heritage is a field of contested meanings, institutional decisions, linguistic practices, editorial choices and social uses of the past. When a dictionary defines a term, when an archive catalogues a personal fund, when a literary database includes an exile author, when a historian publishes a source edition, heritage is being actively structured. Such work determines what later generations can recognise as part of their cultural inheritance. The Academy's responsibility is therefore both conservative and critical. It conserves materials, but it also makes them available for reinterpretation.

The public dimension of this work became stronger after the Academy adopted a more explicit orientation towards research in the public interest. The humanities fit this orientation naturally, although their usefulness is not always measurable in immediate economic terms. They help society understand language, law, memory, political identity, cultural transmission, historical trauma and democratic institutions. This kind of knowledge may not produce a patent, but it produces civic intelligibility. The Academy's mission statement emphasises research across a broad spectrum of sciences and the humanities while taking into account the needs of Czech society and national culture. In the humanities, those needs are often needs for continuity, interpretation and public reason rather than technological application (Academy of Sciences of the Czech Republic, n.d.).

The Academy also guards memory by creating trusted expert communities. In public debates about history, language, literature or cultural identity, expertise is often challenged by political emotion, media simplification or ideological mobilisation. The Academy's authority does not

come from claiming final ownership of truth, but from sustaining communities trained in evidence, method, peer review and disciplinary debate. This is why long-term institutes matter. They provide continuity beyond electoral cycles, media scandals and commemorative anniversaries. They allow scholars to build projects that require decades rather than months. In this sense, the Academy's guardianship of memory is inseparable from its institutional stability.

The relationship between memory and autonomy remains central. If the Academy were merely an arm of the state, its memory work would risk becoming official history. If it were merely a collection of private researchers, it might lack the capacity to maintain national scholarly infrastructure. Its post-1989 model attempts to hold together public support and scientific autonomy. This balance is particularly important in the humanities, where the objects of research often touch upon national identity, political legitimacy and collective trauma. The Academy must be public enough to serve society, but autonomous enough to disagree with comforting myths. Its guardianship is valuable only because it is scholarly, not ceremonial.

The Academy's role in preserving scholarly memory also reaches beyond Czech society into international scholarship. Digital libraries, bibliographical databases, critical editions and archival guides make Czech materials available to foreign researchers and to Czech studies abroad. They help prevent Czech history and literature from being trapped inside a linguistic or national enclosure. This is crucial for a small-language scholarly culture. Without organised access, foreign knowledge of Czech culture easily becomes dependent on translated fragments, famous names or politically fashionable themes. The Academy's infrastructure allows Czech topics to enter comparative research on Central Europe, nationalism, communism, exile, language culture and literary modernity.

One of the most important consequences of the post-1989 transformation was the replacement of controlled memory with plural memory. Under ideological rule, the state attempted to define which pasts were usable, which names were honourable and which questions were dangerous. The democratic Academy could not and should not impose a single counter-memory. Its function was to create conditions for multiple, evidence-based and critically examined memories to coexist. This included memories of victims and dissidents, but also memories of everyday life, compromise, reform communism, regional culture, minorities and institutions. The Academy's humanities thus helped Czech society move from the politics of silence to the discipline of inquiry.

This does not mean that the Academy's memory work is free of tension. Public expectations often demand quick answers, while scholarly infrastructure moves slowly. Funding systems may prefer short-term projects, while archives, dictionaries and editions require long continuity. Digital access may create new audiences, but it also requires resources, preservation strategies and intellectual curation. Memory politics can make some topics emotionally charged, while scholarly integrity requires patience. The Academy's task is to manage these tensions without abandoning the deeper logic of humanities research. Its guardianship is therefore not a finished achievement but an ongoing institutional practice.

The Academy's guardianship of cultural and scholarly memory is especially visible when seen against the full arc of Czech scientific history. From early learned societies and the national revival through the Czech Academy of Sciences and Arts, the Czechoslovak Academy of Sciences and the modern Czech Academy of Sciences, knowledge institutions have repeatedly carried more than research functions. They have helped define what counted as national

culture, scientific authority, public reason and intellectual continuity. After 1989, this long history could be reinterpreted without the old ideological frame. The Academy could recognise its predecessors while also acknowledging rupture, political dependence and reform. In doing so, it became not only the heir of earlier institutions but also their historian.

Thus, the Academy's role as guardian of cultural and scholarly memory after 1989 should be understood as one of the defining features of its humanities mission. It preserved archives, libraries, dictionaries, bibliographies, editions, databases, scholarly journals and personal fonds, but it also transformed these resources into instruments of democratic self-understanding. Its historians, philosophers, linguists and literary scholars helped Czech society recover suppressed traditions, examine compromised institutions, preserve linguistic and literary inheritance, and reconnect national culture with European and international scholarship. This guardianship was never merely conservative, because memory in a democratic research institution is not the passive protection of relics. It is the active, critical and methodical preservation of the conditions under which a society can continue to know, question and reinterpret itself.

Czech Language, Literature, and Cultural Identity

1. Linguistic Research and National Language Culture

The study of the Czech language within the Academy has always occupied a position that is more than technical, disciplinary or narrowly philological. Czech linguistics has been tied to the history of national self-definition, to the authority of written culture, to the public function of education and to the delicate relation between scholarly description and language cultivation. After 1989, this older connection did not disappear; rather, it had to be reinterpreted in a democratic, plural and increasingly European context. The Czech language was no longer to be defended through the rhetoric of ideological guardianship, nor through a rigid understanding of national purity. It had to be studied as a living historical and social system, shaped by everyday usage, public institutions, media, literature, regional variation, technological change and contact with other languages. The Academy's linguistic work therefore became one of the most visible ways in which the humanities connected national culture with empirical research and public service. In this field, the Academy was not simply a keeper of tradition, but a mediator between tradition and change (Czech Language Institute, n.d.; Sayer, 1998).

The institutional roots of this role reach back to the late 19th century, when the creation of the Czech Academy of Sciences and Arts gave the national language a central place in organised scholarly work. The task of preparing a large explanatory dictionary of Czech was not a merely lexicographical undertaking. It was also a cultural act, because the national language was treated as a foundation of modern Czech intellectual life. The creation of the Office of the Dictionary of the Czech Language in 1911 reflected the belief that a national scholarly institution should document, stabilise and interpret the language through which the nation understood itself. The later transformation of this office into the Czech Language Institute in

1946 widened the programme from dictionary work to dialectology, language history and the study of contemporary standard Czech. When the institute entered the Czechoslovak Academy of Sciences in 1953, it became one of the anchor institutions through which the socialist Academy inherited much older philological and national-cultural obligations (Czech Language Institute, n.d.; Digital Humanities Czech Academy of Sciences, n.d.).

The post-1989 transformation gave this inheritance a new political and intellectual meaning. During state socialism, language research did not suffer ideological intervention in exactly the same way as contemporary history, philosophy or sociology, but it was still embedded in a system that preferred centralised authority, regulated public expression and institutional hierarchy. Language cultivation could easily be understood as part of a broader culture of norm, correction and discipline. After the Velvet Revolution, linguistic authority had to be re-legitimated in a different public sphere. The Czech Language Institute could no longer speak as if a scholarly recommendation were an administrative command; instead, it had to explain, advise, contextualise and persuade. This shift did not weaken the institute's role. On the contrary, it made its expertise more publicly meaningful, because democratic society needs language guidance precisely when communication becomes freer, more diverse and more unstable.

The return of František Daneš to the directorship after the Velvet Revolution symbolised this connection between scholarly continuity and democratic renewal. Daneš represented the high tradition of Czech linguistics associated with functional, textual and communicative approaches to language. His post-1989 position was important not because one scholar could determine the future of the discipline, but because his return signalled that linguistic research would not simply continue as an inherited administrative structure. It would reconnect with interrupted lines of professional authority and with broader European linguistic debate. In this sense, the transformation of linguistic research after 1989 was less dramatic than the creation of the Institute of Contemporary History, but no less significant. It showed how a discipline with strong pre-socialist and socialist-era continuity could adapt to a democratic cultural environment without abandoning its accumulated expertise.

The older Prague linguistic tradition remained one of the intellectual backgrounds of this renewal. Czech linguistics had been internationally visible since the interwar period through the Prague Linguistic Circle, whose functional and structural approaches shaped phonology, stylistics, literary theory and the theory of the standard language. Bohuslav Havránek's work on the functional differentiation of the standard language was particularly important because it treated standard language not as a static ideal but as a system serving different communicative functions. This tradition allowed Czech linguistics to resist simple purism and to think about normativity in relation to usage, function, style and social need. After 1989, such ideas became newly relevant because the public sphere was expanding rapidly. Journalism, advertising, political debate, private business, higher education and electronic communication all placed pressure on established forms of standard Czech (Havránek, 1932/1964; Garvin, 1964).

The concept of national language culture therefore had to be modernised. In the 19th century, language culture was often associated with national revival, codification and the struggle for Czech as a full language of education, administration, science and literature. In the 20th century, it became connected with standardisation, schooling, public correctness and the authority of linguistic institutions. After 1989, however, the Czech language entered a

communicative environment in which pluralism, informality and social differentiation became more visible. The rigid opposition between correct and incorrect usage could no longer carry the whole burden of linguistic public service. Linguists had to explain why certain forms are standard, why others are colloquial or regional, how style depends on context, and how language norms change over time. The Academy's contribution was to replace moralised correction with informed interpretation.

This did not mean abandoning the idea of standard Czech. On the contrary, standard Czech remained essential for education, public administration, law, scholarship, journalism and cultural continuity. A modern democratic society needs a shared written and formal language in which institutions can communicate with citizens and citizens can participate in public life. The question was how this standard should be understood. If treated as an untouchable relic, it becomes alien to living speakers; if dissolved completely into everyday variation, it loses its integrative function. Czech linguistics after 1989 had to negotiate this balance with particular care because the Czech language situation includes a strong difference between standard Czech, colloquial forms, regional varieties and the widely discussed phenomenon of Common Czech. The Academy's language research provided the conceptual tools for understanding this complexity without turning it into a cultural panic.

The Czech Language Institute's departments reflect the breadth of this task. Research in grammar, lexicology, lexicography, dialectology, etymology, onomastics, stylistics, sociolinguistics and historical language development allows Czech to be studied as a full linguistic system across time, space and social use. Grammar examines the structure of contemporary Czech and its descriptive models. Lexicology and lexicography monitor vocabulary, neologisms, semantic change and dictionary representation. Dialectology preserves regional speech forms that carry deep historical memory. Etymology connects Czech words with Slavic and broader Indo-European histories. Onomastics studies proper names, which link language with territory, identity, family history and public administration. Stylistics and sociolinguistics examine the use of language in society, media, institutions and everyday interaction (Digital Humanities Czech Academy of Sciences, n.d.).

The importance of dialectology is especially clear in a national culture whose language has often been imagined through the prestige of written standard forms. Dialects and regional speech forms in Bohemia, Moravia and Silesia preserve linguistic histories that cannot be captured by standard grammar alone. They record settlement patterns, social relations, contact with neighbouring languages and local forms of identity. After 1989, regional variation acquired renewed cultural value because democratic society could more openly recognise internal plurality. Dialectological research therefore served both science and cultural memory. It showed that the national language is not a uniform block but a historically layered field. The Academy's work in this area helped protect local linguistic traditions from disappearance or folkloric simplification.

Onomastics also demonstrates the public dimension of linguistic research. Proper names are not merely labels; they carry legal, familial, historical and cultural significance. Personal names, surnames, place names and institutional names often become sites where language, identity and public administration meet. The Czech Language Institute's expert work on names and surnames is therefore part of a broader system of linguistic authority in civic life. Such expertise matters in registration, legal documents, spelling conventions, minority names, foreign names and the adaptation of names into Czech grammatical and orthographic

systems. In this field, the Academy's knowledge becomes practically relevant without ceasing to be scholarly. It helps society manage the everyday consequences of linguistic tradition and change.

The Language Consulting Centre is one of the most visible public interfaces of the Academy's linguistic mission. It assists Czech language users with spelling, inflection, conjugation, word meanings, etymology, usage, sentence formulation and interpretation. This service reveals a distinctive feature of Czech language culture: expert linguistic advice is not confined to academic journals but enters the lives of teachers, editors, journalists, civil servants, students, lawyers, writers and ordinary citizens. The consultation centre also transforms public questions into material for linguistic research, popularisation, codification and statistical analysis. In this sense, the relationship between the institute and society is reciprocal. The institute provides expertise, while public language problems reveal where norms are changing, where uncertainty arises and where research needs to become more communicative (Czech Language Institute, n.d.).

This public service role became more important after 1989 because the democratisation of public speech increased both freedom and uncertainty. Political language changed rapidly as the vocabulary of party orthodoxy disappeared and the language of democracy, civil society, markets, European integration and human rights entered public use. Journalism became more diverse, advertising expanded, private business created new registers, and the internet later transformed the speed and informality of communication. These changes did not simply add new words. They altered the social conditions under which language norms were negotiated. Linguists had to observe how foreign terms, bureaucratic formulas, media clichés, political metaphors and colloquial expressions entered the public sphere. National language culture became less a matter of guarding a closed inheritance and more a matter of helping a society speak precisely under conditions of rapid change.

The contact with English after 1989 is a particularly revealing example. English became increasingly important in business, science, higher education, technology, popular culture and European communication. For Czech language culture, this created both enrichment and anxiety. Borrowings, calques, hybrid constructions and terminology entered Czech at great speed. Some were necessary because new realities required new names; others were fashionable or imitative; still others reflected the globalisation of professional and digital life. The Academy's linguistic role was not to condemn foreign influence mechanically, because Czech has always developed through contact. Its task was to distinguish functional borrowing from unnecessary opacity, to explain adaptation, and to preserve the capacity of Czech to operate as a full language of science, administration, education and culture.

The question of Czech as a language of science is especially important for the Academy. On one hand, internationalisation requires Czech researchers to publish in English, participate in global debates and use international terminology. On the other hand, if Czech loses its ability to express specialised knowledge, national public culture becomes dependent on translation, simplification or foreign-language mediation. Linguistic research therefore belongs to the infrastructure of national scholarly sovereignty. Dictionaries, terminology, academic writing support and language cultivation allow Czech to remain a medium of sophisticated thought. This is not linguistic nationalism in a narrow sense. It is the recognition that a democratic society should be able to discuss complex matters in its own language while remaining open to international exchange.

The development of electronic resources changed the practical form of language culture. The Internet Language Reference Book, online dictionaries, digital lexical archives and other electronic tools made linguistic expertise accessible to a much broader public. Instead of relying only on printed manuals, users could consult electronic resources quickly and repeatedly. This altered the relationship between authority and access. Linguistic guidance became less ceremonial and more integrated into everyday writing practices. Digital resources also made the institute more visible to younger generations who encounter language problems through computers, mobile devices and online communication. The Academy's traditional role in codification thus entered a new technological environment (Czech Language Institute, n.d.; Digital Humanities Czech Academy of Sciences, n.d.).

Corpus linguistics introduced an even deeper methodological change. Although the Czech National Corpus is institutionally linked to Charles University rather than the Czech Academy of Sciences, its development has strongly affected Czech linguistic research as a whole. Founded in 1994, the Czech National Corpus project aims to map Czech in written, spoken, historical, regional and genre dimensions through large electronic text collections. It provides authentic language data for research in linguistics, social sciences, humanities and natural language processing. This empirical infrastructure shifted attention from isolated examples and prescriptive intuition towards large-scale evidence about actual usage. It also encouraged cooperation between grammar, lexicography, stylistics, sociolinguistics, computational methods and language teaching (Charles University, n.d.; Institute of the Czech National Corpus, n.d.).

For the Academy's linguistic culture, corpus evidence did not abolish normativity, but it changed its basis. A language recommendation that ignores real usage risks becoming artificial; a recommendation based only on frequency risks losing the social function of the standard language. Corpus data allow linguists to see how forms are distributed across genres, regions, periods and communicative situations. This makes it possible to formulate more nuanced judgements about language change. It also helps distinguish temporary fashion from stable development and private impression from documented tendency. In this sense, corpus linguistics strengthened rather than weakened responsible language cultivation. It made the public norm more empirical.

The Czech National Corpus also widened the cultural archive of Czech. Its resources include written synchronic corpora, web corpora, learner corpora, spoken corpora, dialect corpora, diachronic corpora, parallel corpora and specialised corpora, including materials connected with public speech, science, poetry and the language of the communist regime. Such diversity transforms language into a historical and social dataset. It allows researchers to study not only grammar and vocabulary but also discourse, ideology, register, genre and communicative style. This is important for the Academy's broader humanities mission because language becomes a bridge between linguistics, history, literary studies, sociology and digital humanities. The corpus does not replace archives, dictionaries or editions; it adds a new dimension to them (Czech National Corpus, 2026).

The post-1989 period also encouraged a more sociolinguistic understanding of Czech language culture. Questions of language are inseparable from education, social mobility, region, generation, gender, media and institutional power. The way people speak and write can affect their access to authority, employment, cultural recognition and educational success. Linguistic research therefore has a democratic dimension. It can expose how norms include

and exclude, how standard language is learned, how non-standard forms are evaluated, and how linguistic insecurity is produced. A mature national language culture must not humiliate speakers for variation, but it must also provide access to the standard forms required in public life. The Academy's expertise can help maintain this balance by combining respect for variation with commitment to clear and cultivated communication.

Language teaching and language education form another important area of connection between research and society. The Academy is not primarily a school system, but its linguistic work affects textbooks, teacher training, dictionaries, grammar descriptions, consultation services and public understanding of Czech. After 1989, Czech education had to move away from ideological formulas and towards more open civic and cultural formation. Language education played a central role in this transition because pupils encounter public culture through reading, writing, interpretation and argument. Linguistic research could support this process by clarifying grammar, style, textual coherence, vocabulary and the relation between spoken and written Czech. In this sense, the Academy contributed indirectly to the formation of democratic citizens.

The cultural significance of Czech linguistics is also visible in its relation to literature. Language and literature cannot be separated in the Czech tradition, because the national revival, literary canon and standard language developed in close contact. Literary works influence vocabulary, style and cultural prestige, while linguistic scholarship provides tools for understanding textual form and historical usage. After 1989, the reinterpretation of Czech literature required renewed attention to language variation, exile language, samizdat style, censorship, translation, regional speech and the rhetoric of official discourse. Linguistic research therefore supported literary studies by making the language of texts historically and socially legible. This connection prepares the ground for the later discussion of literary heritage, but it also belongs to language culture itself.

The relation between Czech and Slovak after the dissolution of Czechoslovakia created another important linguistic and cultural question. The split of the federal state in 1993 did not erase mutual intelligibility, shared media memories or personal bilingual experiences. Yet younger generations gradually encountered Slovak differently from those who had lived in the common state. Czech language culture therefore had to reckon with a changed political environment in which Slovak was no longer the second language of a common federation but the language of a neighbouring state with deep historical proximity. This development raised questions about linguistic contact, passive bilingualism, education, media exposure and Central European cultural memory. The Academy's broader humanities context made it possible to understand Czech not in isolation but in relation to Slovak and other neighbouring languages.

The Academy's linguistic work also participates in the protection of historical depth. The study of Old Czech, historical grammar, etymology and earlier textual traditions reminds society that contemporary language is the result of long development. Historical linguistics prevents national language culture from becoming trapped in present-day disputes over correctness. It reveals how forms that now seem natural were once innovations, how meanings shifted, how foreign influence was absorbed, and how written norms emerged from complex cultural processes. This long perspective is intellectually stabilising. It teaches that language change is normal, but also that continuity requires documentation and interpretation. The Academy's

historical linguistic research therefore deepens the public understanding of both change and inheritance.

The status of Czech as a small but fully developed European language gives special importance to institutional linguistic support. Large global languages often rely on vast publishing markets, international academic systems and commercial technologies to maintain their visibility. Smaller languages require deliberate scholarly infrastructure to remain competitive in science, administration, digital communication and cultural production. The Czech Academy's linguistic work is part of this infrastructure. It ensures that Czech has dictionaries, grammars, databases, advisory services, historical records and expert communities capable of responding to modern needs. Without such institutions, language culture would become either fragmented or dependent on informal opinion.

The digital age has made this support more urgent rather than less. Automatic translation, search engines, speech recognition, language models and digital publishing all depend on high-quality linguistic data. Czech can participate effectively in these technologies only if it possesses corpora, dictionaries, annotated resources, terminology and computationally usable descriptions. Although much natural language processing work is conducted at universities and specialised technological centres, the Academy's linguistic and lexicographical resources remain part of the broader ecosystem. The future of national language culture increasingly depends on the connection between classical philology and digital language technology. This is one of the most important transformations of the post-1989 period.

The public authority of the Czech Language Institute also raises a subtle question: how can an expert institution guide language without appearing authoritarian? The answer lies in the distinction between codification, recommendation and explanation. Codification identifies forms accepted as standard in particular contexts. Recommendation advises users on appropriate choices. Explanation shows why variation exists and how meanings, styles or forms differ. A democratic language culture needs all three, but it must avoid reducing language to a system of prohibitions. The Academy's strongest contribution is educational rather than punitive. It helps speakers become more conscious users of their language.

This consciousness is not only grammatical. It is also cultural and civic. Public language can clarify or obscure responsibility; it can include or exclude citizens; it can create trust or manipulation. The study of style, discourse and sociolinguistics therefore belongs to the wider democratic mission of the humanities. After 1989, Czech public life had to learn new vocabularies of law, democracy, market economy, European integration, human rights and civil society. It also had to identify the residues of ideological language inherited from the previous regime. Linguistic research could contribute to this process by analysing public discourse, naming clichés and showing how language shapes political perception.

The Academy's linguistic mission thus stands between memory and modernisation. It preserves the historical depth of Czech, maintains lexicographical and dialectological traditions, and protects the continuity of standard language. At the same time, it responds to new communication technologies, global English, digital corpora, public consultation, sociolinguistic diversity and changing media practices. This duality is precisely what makes linguistic research central to national culture. A language that only preserves itself becomes rigid; a language that only changes loses memory. The Academy helps Czech society live inside this tension without reducing it to fear or fashion.

Thus, linguistic research after 1989 became one of the most important humanities fields through which the Czech Academy of Sciences linked national identity, public culture and modern scholarship. The Czech Language Institute inherited the dictionary-making and language-cultivation traditions of earlier learned institutions, but it redefined them within a democratic, plural and technologically changing society. Its work in grammar, lexicography, dialectology, etymology, onomastics, stylistics, sociolinguistics, historical language development and public consultation helped maintain Czech as a language of education, science, administration, literature and everyday civic life. At the same time, cooperation with corpus-based and digital resources transformed language culture from a primarily prescriptive enterprise into an evidence-based and publicly accessible field of knowledge. The Academy's contribution therefore lay not in freezing the Czech language as a national relic, but in sustaining the scholarly and civic conditions under which it could continue to develop as a living European language.

2. Literary Studies and the Reinterpretation of Czech Cultural Heritage

The reinterpretation of Czech cultural heritage after 1989 cannot be understood without literary studies, because literature had long served as one of the principal languages through which Czech society imagined itself. From the national revival onwards, the literary word was never merely aesthetic; it was connected with language, education, collective memory, political legitimacy and the symbolic continuity of the nation. This gave Czech literary scholarship a public weight that exceeded the boundaries of textual interpretation. After the Velvet Revolution, however, this heritage could no longer be approached through the inherited categories of national celebration or socialist cultural pedagogy. The literary archive had been fractured by censorship, exile, samizdat, ideological criticism, compromised publishing institutions and the selective school canon. The task of the Academy's literary studies was therefore not simply to "restore" Czech literature to a pre-communist form. It had to reinterpret the whole cultural field as a historically divided, multilingual, politically pressured and aesthetically heterogeneous inheritance (Macura, 1995; Holy, 1996; Sayer, 1998).

The Institute of Czech Literature of the Czech Academy of Sciences occupied a central place in this process because it carried both institutional continuity and the memory of institutional distortion. Established in 1947 by the Czech Academy of Sciences and Arts, incorporated into the Czechoslovak Academy of Sciences in 1953, expanded through the Brno branch and the theatre studies centre, and transformed in 1970 into the Institute for Czech and World Literature, it reflected the changing political and cultural conditions of Czech literary scholarship. The adoption of its present name in 1993, connected with a return to the original concept of Czech studies, was therefore symbolically important. It suggested that literary scholarship after 1989 was not merely adding new topics to an old framework, but redefining the object of study itself. Czech literature was to be studied from the earliest period to the present as a complex cultural formation, not as a politically filtered sequence of approved works. The institute's emphasis on literary history, literary theory, lexicography and literary-science information made it a key institution for this reconstruction (Institute of Czech Literature of the CAS, n.d.; Digital Humanities Czech Academy of Sciences, n.d.).

The first and most visible post-1989 challenge was the reintegration of authors and texts that had been excluded from official literary life. Communist cultural policy had divided Czech literature into official, tolerated, prohibited, samizdat and exile spheres, although the borders

between them were often porous and historically changeable. Some authors moved between publication and silence; some published abroad while remaining culturally Czech; some appeared in samizdat but not in state publishing houses; some were allowed in limited editions only after compromise or ideological reinterpretation. After 1989, literary studies had to rebuild this broken map. It was not enough to insert the names of banned writers into existing literary histories. Scholars had to reconstruct the conditions of circulation, reception, censorship, readership, editorial mediation and textual variation that had shaped their works (Holy, 1996; Machovec, 2009; Přibáň et al., 2018).

This reconstruction required a change in the concept of the literary canon. Before 1989, the school and public canon had been shaped by a combination of older national tradition and ideological selection. Writers who could be presented as progressive, realist, socially engaged or compatible with official interpretations were privileged, while Catholic, liberal, existential, experimental, dissident and exile voices were often marginalised or suppressed. After 1989, the temptation was to construct a counter-canon based on moral rehabilitation alone. Yet such a solution would have reproduced the old habit of making literature serve a political hierarchy, even if the hierarchy had changed direction. The more difficult task was to create a plural canon in which aesthetic achievement, historical witness, textual complexity and cultural influence could be considered together. Czech literary heritage had to be reopened as a field of arguments rather than stabilised as a new list of heroes.

The recovery of samizdat literature was particularly important because it revealed that literary life under communism had not simply stopped outside official publishing. Samizdat created alternative circuits of writing, copying, editing, binding, distributing, reading and discussing texts. It was literary, political, social and technical at the same time. Its products included poetry, prose, essays, philosophical texts, religious reflections, memoirs, manifestos, journals and almanacs. To study samizdat only as “resistance literature” would be too narrow, because it also created communities, aesthetic experiments, editorial practices and forms of cultural sociability. The Academy’s work on samizdat therefore helped transform an underground memory into a scholarly field, with bibliographies, encyclopaedic entries, archival description and contextual interpretation (Přibáň et al., 2018; Přibáňová, 2021).

Exile literature posed a related but distinct problem. Exile writers were geographically outside the state but not outside Czech cultural history. Their works circulated through foreign publishers, émigré journals, radio broadcasts, smuggled books, personal networks and later translations. They preserved linguistic, political and literary continuities that domestic institutions often could not maintain openly. Yet exile also changed literary identity: writers addressed different audiences, lived in new languages, entered foreign cultural markets and sometimes became more internationally visible than domestically present. After 1989, literary studies had to overcome the artificial separation between domestic and exile literature. This required bibliographical precision and interpretative tact, because exile was not simply a heroic supplement to national literature, but one of the ways in which Czech culture survived its political fragmentation (Bolton, 2012; Czech Literary Bibliography, n.d.).

The reintegration of exile and samizdat also changed the interpretation of official literature. It became impossible to treat officially published works either as simple instruments of the regime or as aesthetically neutral texts untouched by politics. Writers who published in official channels did so under different conditions: some were loyal to the system, some compromised, some used coded language, some withdrew into private themes, some

exploited gaps in censorship, and some shifted position over time. Literary scholarship therefore had to read official literature with the same complexity that it applied to unofficial culture. The division between official and unofficial was historically real, but not analytically sufficient. The value of post-1989 reinterpretation lay in examining how censorship, self-censorship, genre, metaphor, irony, editorial mediation and readership shaped the literary text itself (Holy, 1996; Bren, 2010).

The literary heritage of the 20th century became especially charged because Czech literature had repeatedly encountered political catastrophe. The Nazi occupation, the Holocaust, the Stalinist years, the Prague Spring, the invasion of 1968, normalisation and the final crisis of the regime all left traces in literary form. Some works responded directly through testimony, satire or political reflection. Others registered trauma indirectly through silence, fragmentation, absurdity, grotesque humour, existential unease or the retreat into everyday detail. Post-1989 literary studies had to read these forms not as mere illustrations of history but as specific modes of historical experience. Literature could preserve what administrative documents and political speeches could not: ambiguity, fear, shame, irony, compromised intimacy and the texture of ordinary life under pressure.

The reinterpretation of Czech cultural heritage also meant returning to older periods with new questions. Medieval, early modern and 19th-century literature had not been censored in the same way as contemporary writing, but their interpretation had often been shaped by national teleology. The national revival, in particular, had long been treated as the heroic rebirth of the Czech nation through language and literature. After 1989, scholars could examine it more critically as a cultural construction involving philology, mythology, translation, social ambition, urban culture, political imagination and symbolic invention. This did not diminish the importance of the revival. Rather, it made it more historically intelligible. Czech literary heritage became less a sacred origin story and more a dynamic cultural process (Macura, 1995; Sayer, 1998).

The question of Czech-German relations also gained renewed significance. The literary history of the Bohemian lands cannot be reduced to Czech-language literature alone, because German-language writing, Jewish culture and bilingual intellectual life formed an essential part of the region's cultural landscape. Prague German literature, including figures such as Franz Kafka, Max Brod and their circles, had long complicated national literary categories. After 1989, the broader Europeanisation of Czech cultural memory encouraged literary studies to treat multilingual and interethnic contexts not as peripheral but as constitutive. The Czech canon could therefore be reinterpreted within the wider history of Central Europe, Habsburg culture, Jewish memory, borderland experience and translation. This was one of the most important ways in which literary studies helped move cultural identity beyond a closed national frame (Agnew, 2004; Sayer, 1998).

Literary theory also underwent a necessary repositioning. Under socialism, theory had been shaped by a complex mixture of Marxist vocabulary, structuralist inheritance, semiotics, textual analysis and the uneven reception of Western approaches. Czech structuralism and the Prague School had remained internationally significant, but their domestic institutional position had been affected by political conditions. After 1989, literary scholars could more freely engage with hermeneutics, reception theory, narratology, post-structuralism, gender studies, memory studies, cultural studies and comparative theory. Yet the best work did not merely import theoretical fashions. It used new frameworks to reinterpret Czech materials

while also recovering the specific strength of Czech structuralist and semiotic traditions. The renewal of literary studies therefore involved both internationalisation and the reactivation of domestic theoretical memory.

The Institute of Czech Literature's combination of literary history, theory and lexicography was especially suitable for this task. Lexicographical work in literary studies may seem less visible than interpretative monographs, but it is crucial for reconstructing cultural heritage. Dictionaries of writers, movements, terms, journals, institutions and post-1945 literature create the reference architecture within which later interpretation takes place. They also correct earlier exclusions by documenting authors, editors, publishers and periodicals that had been absent from official cultural memory. The Dictionary of Czech Post-1945 Literature and related databases show how the Academy transformed literary rehabilitation into structured knowledge. In this sense, reinterpretation was not only an essayistic or theoretical activity. It was also archival, bibliographical and lexicographical labour (Digital Humanities Czech Academy of Sciences, n.d.; Digital Humanities Czech Academy of Sciences, n.d.).

The Czech Literary Bibliography became one of the most important infrastructures for this reinterpretation. It carries on a long tradition of specialist bibliographical work at the Institute of Czech Literature and systematically maps literary life in the Czech lands from the beginnings of the national revival to the present. Its databases include materials on literary science, periodicals, journals, cultural journalism, scholarly press, book publications, exile literature and associated humanities disciplines. This infrastructure is not only a tool for specialists; it is a cultural map. It allows researchers to trace reception, polemics, translations, reviews, forgotten publications, regional periodicals and the movement of literary ideas across time. Without such bibliographical infrastructure, the reinterpretation of heritage would remain dependent on selective memory and well-known names (Czech Literary Bibliography, n.d.; Digital Humanities Czech Academy of Sciences, n.d.).

The Retrospective Bibliography of Czech Literature is especially significant because it preserves a documentary universe that predates and exceeds modern disciplinary boundaries. It covers periodicals published in the Czech lands in Czech, German and Slovak from the beginning of the national revival to the end of the Second World War, excerpting fiction, reviews, literary-scientific studies, essays, reports, comments, polemics, journalism and related materials. Its card catalogue, consisting of hundreds of drawers and approximately 1.75 million citation slips, represents a monumental form of scholarly memory. The ongoing digital accessibility of these materials turns a physical archive into a wider research infrastructure. This project demonstrates that cultural heritage is not only made of canonical books. It is also made of reviews, minor debates, periodical fragments, forgotten images and the everyday printed life of a literary culture (Digital Humanities Czech Academy of Sciences, n.d.).

The digital transformation of literary studies did not replace the older philological virtues of patience, accuracy and textual criticism. Instead, it expanded the scale at which those virtues could operate. Digital bibliographies, databases of literary figures, databases of book editions, digitised journals, rhyme databases, metrics tools and digital archives of popular literature made it possible to ask new questions about networks, circulation, genres, forms and reception. The Institute of Czech Literature's digital resources show that the reinterpretation of heritage now involves both close reading and data organisation. Scholars can still interpret individual poems, novels and essays, but they can also trace patterns across thousands of

publications. This is one of the clearest signs that the Academy's humanities have moved from post-1989 recovery towards 21st-century research infrastructure (Digital Humanities Czech Academy of Sciences, n.d.; Czech Literary Bibliography, n.d.).

The reinterpretation of Czech cultural heritage also required attention to popular literature. Earlier literary histories often privileged high culture, national classics and ideologically significant authors. Yet popular genres, periodical fiction, children's literature, detective stories, science fiction, humour, theatre, song texts and mass readerships are also part of cultural history. They reveal how society imagined morality, adventure, gender, class, nation, modernity and everyday life. The Academy's digital archive of popular literature and related bibliographical resources helped broaden the literary field beyond a narrow canon. This widening is not a lowering of scholarly standards. It is the recognition that cultural identity is produced not only by masterpieces but also by ordinary reading practices.

The relationship between literature and theatre is another important dimension. Czech cultural memory has often been theatrical as well as literary, from the National Theatre as a symbol of the 19th-century national movement to the public role of playwrights and theatre communities in the 20th century. The historical incorporation of the Centre for the Study of Czech Theatre into the Institute of Czech Literature reflected the close relationship between textual and performative culture. After 1989, this relationship acquired renewed importance because figures such as Václav Havel connected drama, dissent and political transformation. Literary studies therefore had to interpret theatre not merely as a branch of literature, but as a public form of cultural communication. Dramatic texts, performances, censorship records, theatre reviews and audience reception all became part of the reinterpretation of Czech heritage.

The figure of Václav Havel illustrates the difficulty of separating literary, political and cultural memory. Havel was a playwright, essayist, dissident and president, and after 1989 he became one of the most recognisable Czech cultural figures internationally. Literary studies could not treat him only as a political symbol, because his dramatic and essayistic work belonged to the history of absurd theatre, intellectual dissent and moral reflection. At the same time, his political role changed the reception of his writings and the symbolic meaning of Czech literature itself. The scholar's task was therefore to resist both hagiography and reduction. Havel's work had to be placed within literary form, theatrical practice, dissident networks, philosophical vocabulary and post-communist public memory (Bolton, 2012; Suk, 2003).

Bohumil Hrabal, Milan Kundera, Josef Škvorecký, Ludvík Vaculík, Ivan Klíma and many other authors posed different but related interpretative problems. Their works crossed borders between official publication, delayed publication, exile reception, foreign translation, domestic myth and international canonisation. Kundera's French and Czech reception, Škvorecký's exile publishing, Hrabal's negotiations with publication conditions, Vaculík's role in samizdat and Klíma's experience of censorship all show how 20th-century Czech literature cannot be interpreted without the history of institutions. Post-1989 literary studies therefore had to reconstruct not only texts but the conditions under which texts became available, unavailable, altered, translated or remembered. This institutional reading of literature was one of the Academy's strongest contributions to cultural reinterpretation (Holy, 1996; Bolton, 2012).

The reinterpretation of heritage also concerned religious and spiritual writing. Catholic authors, theological reflection, religious poetry and spiritual prose had often been marginalised under communist cultural policy, especially where they conflicted with atheistic ideology. After 1989,

these traditions could be re-examined as part of Czech literary culture rather than as external or reactionary residues. This was important because Czech cultural identity has often been simplistically described through secularism or anti-clerical narratives. Literary history shows a more complex picture, with strong religious, philosophical and ethical currents running through modern Czech writing. The recovery of these currents contributed to a richer understanding of national culture.

Gender became another area in which post-1989 reinterpretation gradually widened the field. Earlier literary histories often centred male authors, male critics and male institutions, while women writers were underrepresented or interpreted through narrow biographical categories. Newer scholarship could ask how gender shaped authorship, readership, genre, publishing, criticism and canon formation. Women's writing under socialism, women in samizdat, feminist thought, memoirs, correspondence and neglected 19th- and 20th-century authors all demanded renewed attention. This did not mean applying an external ideological template to Czech literature. It meant recognising that cultural heritage had been structured by social relations that literary scholarship had often left implicit.

The reinterpretation of cultural heritage also involved translation. Czech literature exists not only in Czech but through its translation into other languages and through the translation of foreign literatures into Czech. Translation shapes international reception, canonisation, publishing networks and the self-understanding of small-language cultures. After 1989, the opening of markets and borders changed the conditions under which Czech literature travelled abroad and foreign literature entered Czech readerships. Literary studies increasingly had to consider translation history, publishing mediation and cultural transfer. This was especially relevant for exile literature, Central European studies and the international reception of Czech modernism, dissent and post-communist writing.

The Academy's literary scholarship also helped separate cultural heritage from political nostalgia. After 1989, the recovery of suppressed literature could easily produce a romantic image of the pre-communist or dissident past. Yet literary history is most useful when it shows contradiction. The First Republic was culturally rich but socially and nationally complex. The socialist period was repressive but also produced significant aesthetic works, complicated compromises and unofficial creativity. Exile preserved freedom but also generated distance, fragmentation and loss. The national revival created modern Czech culture but also constructed myths that later needed critical analysis. The Academy's interpretative role was to make these contradictions visible without dissolving cultural identity into scepticism.

This balance between attachment and criticism is central to the humanities. A national literature cannot be studied well by scholars who despise it, but it also cannot be studied honestly by scholars who worship it. The post-1989 Academy had to cultivate a disciplined affection for Czech cultural heritage: serious enough to preserve, edit and interpret it, but critical enough to question its myths and silences. Literary studies contributed to cultural identity precisely by refusing to reduce identity to comfort. They showed that Czech literature is valuable not because it offers a single moral lesson, but because it records a long struggle over language, memory, freedom, belonging and form.

The public role of literary studies changed in this process. Under state socialism, literary criticism and literary history often had to negotiate censorship, ideological expectations and institutional control. After 1989, they entered a more open but also more market-oriented environment. The cultural authority of literature was no longer guaranteed by the symbolic

prestige of dissent or national tradition. Publishers, media, prizes, schools, universities and digital platforms all shaped reception in new ways. The Academy's literary studies therefore had to justify their public relevance not through ideological authority but through expert knowledge, documentation and interpretation. This was a more demanding but healthier form of legitimacy.

The Institute of Czech Literature's function as an information and consultancy centre in literary-science information shows how scholarly expertise can serve both specialised and public users. Researchers, students, teachers, editors, translators, cultural institutions and interested readers all depend on reliable information about authors, works, periodicals, editions and reception. In a digital environment filled with partial, unsourced or simplified information, the Academy's curated resources become even more important. They provide stability without closing interpretation. They allow cultural heritage to remain accessible, but also verifiable.

The reinterpretation of Czech cultural heritage through literary studies therefore belongs to the larger story of the Academy's post-1989 transformation. It illustrates how autonomy, memory, public responsibility and internationalisation converged in the humanities. Literary scholarship had to recover suppressed materials, confront the institutional history of censorship, rebuild reference infrastructures, widen the canon, internationalise methods and speak to a society rethinking its past. The Academy's strength lay in its ability to combine long-term bibliographical and lexicographical labour with new interpretative questions. This combination made it possible to move beyond the first phase of rehabilitation towards a more mature cultural historiography.

Thus, literary studies after 1989 became one of the principal means by which the Czech Academy of Sciences helped reinterpret Czech cultural heritage. The Institute of Czech Literature and its associated bibliographical, lexicographical and digital infrastructures made it possible to reconnect official, samizdat and exile literature, to recover neglected authors and genres, to rethink the national canon, and to place Czech literature within Central European, multilingual and international contexts. This reinterpretation was not a simple act of restoration, because the literary past itself had been fractured by censorship, exile, ideological selection and institutional compromise. The Academy's contribution lay in turning that fracture into a field of disciplined research. It showed that cultural heritage is not a closed inheritance handed down unchanged, but a living archive that must be edited, documented, questioned and read anew by each generation.

3. Editions, Dictionaries, Corpora, and Digital Humanities

The humanities of the Czech Academy of Sciences after 1989 cannot be understood only through interpretations, monographs or public debates about memory. Much of their real power lay in the less spectacular but more durable infrastructure of scholarly work: editions, dictionaries, bibliographies, corpora, archives, catalogues and digital repositories. These instruments do not simply accompany research; they shape what can be researched at all. A historian without reliable editions of sources, a linguist without dictionaries and corpora, or a literary scholar without bibliographical databases is forced to work through fragments, private memory and accidental availability. The Academy's humanities institutes therefore acted not only as centres of interpretation but as producers of the documentary and technical conditions

of knowledge. After the Velvet Revolution, this function acquired new importance because Czech society was recovering materials dispersed by censorship, exile, institutional rupture and ideological selection. The transition to digital humanities did not abolish the older philological and archival mission of the Academy. It gave that mission new instruments, wider audiences and a new technological form (Czech Language Institute, n.d.; Digital Humanities Czech Academy of Sciences, n.d.; Library of the Czech Academy of Sciences, n.d.).

The tradition of scholarly editions has deep roots in Czech academic culture. From the national revival onwards, the publication of older texts, historical documents, correspondence, literary works and linguistic materials was a way of creating a usable national archive. Editions gave written form to cultural continuity. They also made it possible to distinguish between legend, memory and evidence. In the 19th and early 20th centuries, the editing of medieval, early modern and revival-era texts helped define the contours of Czech literary and historical identity. In the 20th century, source editions and critical editions became even more important because political regimes repeatedly interrupted public access to documents, authors and interpretative traditions. After 1989, editions became one of the means through which suppressed or distorted parts of Czech culture could be returned to scholarly circulation. This was not a mechanical act of publication, but a disciplined process of textual criticism, commentary, contextualisation and bibliographical control.

The Academy's edition work belongs to a broader European humanistic tradition in which the reliability of scholarship depends on the reliability of texts. A critical edition is not merely a reprint. It establishes textual variants, clarifies provenance, identifies editorial interventions, provides explanatory notes and situates the work in its historical and intellectual environment. This is especially important in a culture where censorship, samizdat copying, exile publishing and posthumous editions often created multiple versions of the same text. In Czech literary and philosophical studies, the question "which text?" can be as important as the question "what does the text mean?". After 1989, scholars often had to compare official editions, foreign editions, manuscript versions, samizdat copies and later corrected versions. The Academy's philological competence was therefore essential to the reconstruction of cultural heritage.

Dictionaries represent another fundamental layer of this infrastructure. The Czech Language Institute inherited the dictionary-making tradition of the Czech Academy of Sciences and Arts, including the original task of preparing a major explanatory dictionary of the Czech language. This lexicographical mission was never merely technical, because Czech dictionary-making was historically linked to the development of the standard language, national education and the language of scholarship. The Dictionary of Standard Czech Language, published in print between 1960 and 1971 and later made available online, contains nearly two hundred thousand vocabulary entries with explanations and examples of use. Its digital availability changed the practical relation between the public and linguistic authority. A work that had once belonged primarily to libraries, schools and specialists became accessible to a much broader community of users (Czech Language Institute, n.d.).

The online transformation of dictionaries is one of the clearest examples of continuity through technological change. The scholarly principles of lexicography remained the same: evidence, definition, usage, grammatical description, semantic distinction and historical awareness. Yet the medium altered speed, reach and public expectation. Users could consult dictionaries instantly, compare forms, check meanings and move between related resources. This increased the public visibility of the Czech Language Institute and made linguistic scholarship

part of everyday writing, editing, teaching and administrative practice. Digital access also created new responsibilities, because users often expect immediate and authoritative answers even when language usage is variable or changing. The Academy therefore had to combine accessibility with explanation, resisting the reduction of linguistic knowledge to simple commands.

Historical dictionaries deepen this lexicographical mission by connecting modern Czech with earlier stages of the language. The Old Czech Dictionary, compiled at the Czech Language Institute between 1968 and 2008, describes Czech vocabulary from the earliest written records to 1500 and covers the alphabetical range from N to při in twenty-six volumes. Its importance is not limited to medievalists. It preserves the semantic world of earlier Czech and makes visible the historical depth behind contemporary vocabulary, literature, law, religion and culture. Historical lexicography reminds modern users that language is not a fixed possession but a long process of formation, borrowing, semantic change and textual transmission. In a national culture where language has often served as a symbol of continuity, such dictionaries provide the scholarly evidence for that continuity. They prevent national language memory from becoming a myth detached from textual history (Czech Language Institute, n.d.).

Dialect dictionaries perform a different but equally important cultural function. The Dictionary of Czech Dialects records national dialectal vocabulary and phraseology from the last century and a half, with a core of material from the first half of the 20th century. It preserves the linguistic worlds of Czech, Moravian and Silesian dialects, many of which are disappearing under the pressure of mobility, education, media standardisation and demographic change. This work shows that national language culture does not consist only of the standard language. It also includes local speech, regional memory, agricultural vocabulary, family expressions, names for tools, customs, landscape and everyday life. Dialect lexicography therefore becomes a form of cultural preservation. It records not only words but the social worlds in which those words made sense (Czech Language Institute, n.d.).

The relationship between standard dictionaries, historical dictionaries and dialect dictionaries reveals the richness of the Academy's linguistic infrastructure. Together they show Czech as a system that is simultaneously standardised, historical and regionally varied. The standard dictionary supports public communication, education and administration. The historical dictionary preserves older textual layers. The dialect dictionary captures local and regional speech worlds. None of these dimensions is sufficient alone. A language reduced to standard form loses memory and social texture; a language studied only historically loses contact with living usage; a language approached only through dialects may lose its integrative public function. The Academy's lexicographical work is valuable precisely because it holds these dimensions together.

Literary dictionaries and bibliographical databases perform a parallel function for literature. The Dictionary of Czech Post-1945 Literature, developed from earlier printed dictionaries and updated as an electronic resource, is more than a reference list of writers. It helps reconstruct a literary field fragmented by censorship, exile, samizdat, political rehabilitation and changing scholarly interpretation. Post-1945 Czech literature cannot be mapped adequately through school canon or commercial visibility. It requires systematic information about authors, works, editions, literary groups, reception and publication histories. The digital dictionary transforms this information into a public research tool. It allows teachers, students, scholars, translators

and readers to orient themselves within a complex cultural landscape (Digital Humanities Czech Academy of Sciences, n.d.).

The Czech Literary Bibliography is one of the major infrastructures of Czech literary studies. It continues the long bibliographical tradition of the Institute of Czech Literature and systematically records the literary life of the Czech lands from the national revival to the present. Its value lies in the fact that literature is not made only of books. It is also made of reviews, polemics, literary criticism, periodical essays, scholarly articles, interviews, obituaries, cultural journalism, translations, regional publications and minor printed traces. Bibliography turns this dispersed literary life into searchable knowledge. It allows researchers to study reception, networks, forgotten debates and the changing public presence of authors. Without it, literary history would depend too heavily on canonical memory and easily available texts (Czech Literary Bibliography, n.d.; Digital Humanities Czech Academy of Sciences, n.d.).

The Retrospective Bibliography of Czech Literature demonstrates the scale of this documentary work. It covers materials from Czech, German and Slovak periodicals published in the Czech lands from the beginnings of the national revival to 1945, including fiction, reviews, literary-scientific studies, journalism, reports, polemics and visual excerpts. Its card catalogue contains approximately 1.75 million citation slips, organised in hundreds of drawers, and has been gradually made accessible online through digitisation. This resource shows that cultural heritage is not only a set of famous works. It is an enormous tissue of periodicals, minor publications, translations, forgotten responses and everyday print culture. The digital opening of such a bibliography changes the geography of research because scholars no longer need to rely exclusively on physical access to a local catalogue (Digital Humanities Czech Academy of Sciences, n.d.).

The significance of these bibliographical projects is methodological as well as practical. Bibliography disciplines interpretation by forcing scholars to confront the material record. A literary critic may construct a brilliant reading of an author, but without bibliographical control it is difficult to know how that author was published, reviewed, translated, censored, ignored or rediscovered. Bibliographies reveal the public life of texts. They show when a work entered debate, where it circulated, who responded to it and how its reception changed over time. For a literature affected by exile and censorship, this is especially important. The act of mapping publication and reception becomes part of cultural reconstruction.

The Digital Humanities portal of the Czech Academy of Sciences illustrates the new form taken by these older scholarly traditions. It brings together databases, tools and digital resources produced by Academy institutes, including literary bibliographies, dictionaries, corpora-related resources, archives, databases of literary figures, databases of book editions, digital archives of popular literature, digitised journals and tools for analysing Czech verse. This diversity shows that digital humanities in the Czech Academy did not emerge as an abstract technological fashion. It grew from concrete disciplinary needs: to preserve texts, structure bibliographical data, analyse language, make collections accessible and connect scattered materials. Digital humanities therefore continued the Academy's historical mission of organising knowledge, but under conditions of electronic access, searchability and data interoperability (Digital Humanities Czech Academy of Sciences, n.d.).

Digital tools devoted to Czech poetry are particularly revealing. Databases of Czech metres, rhyme databases, frequency dictionaries of Czech poetry and related analytical tools make it possible to study poetic form at a scale that traditional reading alone could not achieve. This

does not mean that digital analysis replaces interpretation. A rhyme database cannot explain the emotional force of a poem, and a frequency dictionary cannot determine literary value. However, such tools can reveal patterns of metre, sound, vocabulary and form across large bodies of poetic material. They can support historical poetics, comparative literary studies and the study of genre development. In this way, digital humanities expand rather than diminish the older philological attention to form.

Digital archives of popular literature broaden the cultural field in another direction. Traditional literary scholarship often concentrated on canonical authors, high literature and nationally significant works. Yet popular literature shaped reading habits, imagination, humour, social stereotypes, gender roles and everyday cultural consumption. By preserving and organising materials connected with popular genres, the Academy helps researchers study the full ecology of literary culture. This is important for a democratic cultural history because it refuses to identify heritage only with elite works. Cultural identity is formed by classics, but also by popular fiction, periodical entertainment, children's literature, adventure narratives, humour and mass readerships. Digital preservation makes such materials available for serious scholarship without forcing them into the status of canon.

The Library of the Czech Academy of Sciences provides another essential institutional layer. Its Digital Library contains digitised periodicals and monographs produced by the institutes of the Academy and their predecessors, with materials reaching back to the 19th century. This resource preserves the publication output of academic institutions across political regimes, disciplinary changes and institutional reorganisations. It is therefore indispensable for the history of Czech science and scholarship. Digitised Academy periodicals allow researchers to trace how disciplines developed, how terminology changed, how institutes represented themselves and how scholarly communication evolved. The Digital Library also demonstrates that the Academy's memory is not only archival but published, textual and serial (Library of the Czech Academy of Sciences, n.d.; Library of the Czech Academy of Sciences, n.d.).

The digitalisation of Academy publications also changes access to institutional memory. Earlier, many publications were available only in specialised libraries or through personal scholarly networks. Digital access makes them easier to consult, cite and compare. This is particularly important for researchers outside Prague, foreign scholars of Czech studies and interdisciplinary projects that need access to older journals or monographs. It also protects fragile materials from excessive handling while making their contents more visible. In this sense, the Digital Library performs both preservation and democratisation. It keeps scholarly memory alive by removing unnecessary barriers to consultation.

Corpora represent one of the most transformative forms of humanities infrastructure in the late 20th and early 21st centuries. A corpus is not simply a collection of texts; it is a structured, searchable and often annotated body of language data. Corpus linguistics makes it possible to study actual usage across genres, periods, registers, regions and communicative contexts. For Czech linguistic research, corpus methods created a new empirical foundation for grammar, lexicography, stylistics, sociolinguistics, language teaching, translation studies and natural language processing. They shifted part of linguistic authority from intuition and selected examples towards large-scale evidence. This was a major methodological change in the study of contemporary Czech.

The Czech National Corpus, founded in 1994 at Charles University, became the central Czech infrastructure for corpus-based language research. Although institutionally outside the Czech

Academy of Sciences, it is indispensable for understanding the broader ecosystem in which Academy linguistics and digital humanities operate. The project builds and maintains large electronic corpora of written, spoken, historical, regional and specialised Czech, and it provides access to tools for empirical linguistic inquiry. Its corpora include large synchronic written corpora, reference corpora, spoken corpora, dialectal corpora, learner corpora, parallel corpora and historical materials. Such resources have transformed the study of Czech from a predominantly dictionary-and-grammar-based field into a data-rich research environment (Institute of the Czech National Corpus, n.d.; Czech National Corpus, 2026).

The relation between corpora and dictionaries is especially important. Modern lexicography increasingly depends on corpus evidence because dictionaries need to describe how words are actually used, which collocations are typical, how meanings shift and how register affects usage. Corpus data can reveal frequency, context, semantic patterns, phraseology and stylistic distribution. At the same time, corpora do not automatically produce lexicographical meaning. They require trained interpretation, selection and definition. The best dictionary work therefore combines corpus evidence with scholarly judgement. This relationship between data and expertise is one of the defining features of contemporary humanities infrastructure.

Corpora also affect language culture. In older prescriptive traditions, a disputed form might be judged primarily by codified rules or the authority of grammarians. Corpus evidence allows linguists to ask how widespread the form is, in which genres it appears, whether it is increasing, and whether it remains restricted to informal contexts. This does not mean that frequency equals correctness. It means that recommendations can be more realistic and nuanced. For a democratic language culture, this is crucial. Users need guidance that recognises living usage without dissolving the standard language into statistical description.

The digital turn also made possible new forms of interdisciplinary cooperation. Literary scholars can use corpora and databases to examine vocabulary, genre, poetic form, stylistic change and reception. Historians can use digitised periodicals and bibliographies to trace public discourse, political vocabulary and networks of publication. Linguists can work with computational experts on annotation, tagging, morphology and natural language processing. Archivists can cooperate with database designers on metadata and access. Philosophers and intellectual historians can trace concepts across large textual collections. The humanities thus become more technologically mediated, but also more interconnected.

This interdisciplinarity is one of the reasons why digital humanities fit the modern Academy particularly well. The Academy is organised as a network of specialised institutes, each with its own disciplinary traditions and collections. Digital methods make it possible to connect these traditions without dissolving them. A literary database can link to a bibliography, a digitised journal, an author dictionary and a corpus. An archival description can support institutional history, biography, sociology of science and intellectual history. A dictionary can be used by linguists, teachers, editors, computational researchers and cultural historians. Digital humanities therefore translate institutional plurality into research connectivity.

However, the digital transformation also introduces new risks. Searchability can create the illusion that everything important has been found. Databases may privilege what has been digitised over what remains in physical archives. Metadata categories can shape interpretation invisibly. Users may extract isolated fragments without understanding textual context or provenance. The Academy's responsibility is therefore not only to digitise but to curate. Digital humanities require the same critical virtues as traditional humanities: source criticism,

contextualisation, transparency, citation and awareness of absence. Without these virtues, digital abundance can become another form of distortion.

The Academy's role is especially important because digital resources are expensive, technically fragile and institutionally demanding. Databases must be maintained, updated, migrated, documented and protected. File formats change, software becomes obsolete, interfaces require redesign, and long-term preservation must be planned. A digital resource that is built but not maintained may become unusable within a generation. The Academy's public research status gives it a special responsibility to sustain resources beyond short project cycles. In the humanities, where some scholarly tools remain useful for decades, long-term stewardship is as important as innovation.

The move towards open access and public availability has also changed the social meaning of scholarly infrastructure. Earlier, many dictionaries, bibliographies and source editions circulated mainly among specialists. Digital access allows wider publics to consult them: teachers preparing lessons, journalists checking facts, translators verifying usage, local historians searching periodicals, students writing theses, and readers discovering forgotten authors. This wider access does not simplify the resources themselves. Rather, it requires institutions to design interfaces, explanations and guidance that allow non-specialists to enter scholarly materials responsibly. The Academy's digital humanities therefore have an educational and civic dimension.

The digital humanities also help overcome the fragmentation caused by 20th-century political history. Samizdat texts, exile publications, official journals, censored editions, personal papers, bibliographical slips and institutional records were often separated by geography, legality, medium and political status. Digital projects can reconnect these materials in ways that were not possible when each collection remained physically isolated. They can reveal networks between authors, publishers, reviewers, institutions and readers. They can make exile and domestic culture visible within a single research horizon. In this sense, digital humanities continue the post-1989 work of reintegrating Czech cultural memory.

At the same time, digital access does not remove the need for editorial mediation. A scanned page is not the same as a critical edition. An OCR text is not the same as a reliable transcription. A database entry is not the same as a scholarly interpretation. The Academy's traditions of editing, lexicography and bibliography remain essential because digital materials must be verified, described and contextualised. The future of Czech humanities therefore depends not on replacing philologists with technicians, but on creating scholarly teams in which philological, historical, linguistic and technical expertise cooperate. The digital humanities are strongest when they preserve this balance.

The Academy's dictionaries, editions, bibliographies and digital resources also contribute to internationalisation. Czech is a smaller European language, and foreign scholars often depend on organised reference tools to enter its cultural and linguistic history. Digital resources make Czech materials more accessible to researchers abroad, especially when interfaces, metadata or descriptions are available in English or connected to international infrastructures. This does not eliminate the language barrier, but it lowers the threshold for comparative work. It allows Czech literature, language and history to participate more fully in European humanities research. For the Academy, digital infrastructure is therefore also a form of cultural diplomacy.

The relationship between national culture and digital research is not contradictory. Some might assume that digital humanities weaken national traditions by dissolving texts into data or

placing them in global technical systems. In fact, for smaller cultures, digital infrastructure can strengthen cultural presence by making materials findable, citable and reusable. A language, literature or historical tradition that is not digitally represented risks becoming invisible in contemporary scholarship. The Academy's task is therefore to ensure that Czech cultural heritage is not merely preserved in physical collections but present in the digital knowledge environment. This is one of the new forms of national scholarly responsibility in the 21st century.

The post-1989 humanities thus moved through several stages of infrastructure renewal. The first stage involved recovery: opening archives, restoring authors, publishing sources and rebuilding bibliographical control. The second involved consolidation: creating reliable reference works, dictionaries, databases and scholarly editions. The third involved digital transformation: making resources searchable, interconnected and accessible beyond traditional research rooms. These stages did not replace one another in a simple sequence. They overlapped and continue to coexist. The Academy's achievement lies in maintaining the older forms of scholarly discipline while adapting them to new forms of access and analysis.

Thus, editions, dictionaries, corpora and digital humanities form one of the strongest foundations of the Czech Academy of Sciences' humanities mission after 1989. They transform cultural memory into verifiable knowledge, preserve linguistic and literary heritage, support public language culture, enable empirical research and connect Czech scholarship with international digital infrastructures. Their importance lies precisely in their apparent modesty: they do not always produce immediate public drama, but they determine the conditions under which reliable interpretation becomes possible. The Academy's contribution has been to sustain long-term scholarly tools that outlast political fashion, market cycles and media attention. In doing so, it has shown that the humanities are not only about ideas and narratives, but also about the patient construction of the instruments through which a society can continue to read, speak, remember and understand itself.

History, Memory, and Contemporary Society

1. Research on Modern Czech and Czechoslovak History

Research on modern Czech and Czechoslovak history after 1989 became one of the most intellectually and publicly important areas of the humanities within the Czech Academy of Sciences. It was not merely a matter of adding new facts to an existing national story. The modern period itself had to be reassembled, because its interpretation had been repeatedly shaped by political regimes, ideological vocabularies, state anniversaries, school curricula, commemorative rituals and archival restrictions. The 19th-century national movement, the birth of Czechoslovakia, the First Republic, the Munich crisis, the Protectorate, the post-war settlement, the communist seizure of power, Stalinism, the Prague Spring, normalisation, dissent, the Velvet Revolution, the dissolution of the federation and the post-1993 Czech Republic all became fields of renewed scholarly inquiry. Each of these themes had existed before 1989, but many had been surrounded by silences, moral simplifications or official

interpretative schemes. After 1989, the Academy's historians could treat them as open problems rather than as episodes already fixed by doctrine. Modern history became a laboratory in which Czech society could examine its own political identity, its democratic aspirations, its traumas and its unresolved continuities (Kopeček & Kolář, 2007; Agnew, 2004; Sayer, 1998).

The importance of this field derived partly from the fact that modern Czech history is unusually dense in institutional transformations. In less than a century and a half, the Czech lands moved through the late Habsburg monarchy, the First Czechoslovak Republic, Nazi occupation, restored post-war democracy, communist dictatorship, federal socialism, democratic revolution, peaceful state division and European integration. Each transformation altered the relationship between nation, state, citizenship, language, class, religion, region and political legitimacy. Historians therefore had to resist the temptation to present modern Czech history as a straight line from national revival to democratic statehood. The record was too complicated for such a linear narrative. It contained democratic achievement, authoritarian pressure, imperial inheritance, minority conflict, social modernisation, ideological mobilisation and repeated redefinitions of sovereignty. The Academy's contribution was to support research capable of holding these contradictions together without dissolving them into either national self-congratulation or moral exhaustion.

The Institute of Contemporary History became the most visible institution for the study of the recent modern period. Established in 1990, it was founded in direct response to the post-November need for independent research into Czechoslovak and Czech history from 1938 to the present. Its chronological scope was meaningful: 1938 marked the Munich crisis and the collapse of the First Republic's territorial and political security, while the present remained open because the history of communism, transition and democracy was still unfolding. The institute's creation signalled that contemporary history was not a secondary appendix to older national history. It became a central field for understanding Czech society itself. The institute's motto, "To know the past, to understand the present", expresses this dual orientation: historical research was expected to produce specialist knowledge, but also to illuminate the political and moral conditions of the present (Institute of Contemporary History of the CAS, n.d.; Digital Humanities Czech Academy of Sciences, n.d.).

The Institute of History represented another necessary pillar of modern historical research, because contemporary history cannot be separated from longer continuities. The institute, reopened in 1990 after the closure of its socialist predecessor, traced its institutional lineage to the Czechoslovak State Historical Editorial Institute founded in 1920 and incorporated into the Czechoslovak Academy of Sciences in 1953. This continuity mattered because the study of modern Czech history depends on source editions, bibliographies, historical geography, biographical dictionaries and long-term historical infrastructure. The Institute of History offered a broader chronological and methodological framework within which modern events could be linked to medieval, early modern and 19th-century formations of statehood, culture and national identity. The modern period therefore appeared not as an isolated political drama but as part of a longer Czech and Central European historical field (Institute of History of the CAS, n.d.; Digital Humanities Czech Academy of Sciences, n.d.).

The Masaryk Institute and Archives added a third essential dimension by connecting research on modern history with archives of political thought, intellectual life, scientific institutions and the Academy itself. Its collections include archival fonds of the Czechoslovak Academy of

Sciences and the Czech Academy of Sciences, as well as materials related to earlier scholarly institutions and personal papers. This means that modern Czech history can be studied through state politics, but also through the history of experts, institutions, correspondence, academic communities and documentary practices. The Masaryk tradition is especially important because Tomáš Garrigue Masaryk stands at the intersection of philosophy, sociology, democratic politics and national statehood. Research on Masaryk, Edvard Beneš, the First Republic and democratic political culture provided post-1989 Czech society with more than symbolic rehabilitation. It provided a scholarly route back to the foundations and tensions of Czech democracy (Masaryk Institute and Archives of the CAS, n.d.; Masaryk Institute and Archives of the CAS, n.d.).

One of the most important post-1989 changes was the movement from official national narrative to problem-oriented historiography. Under the communist regime, the modern past had often been ordered around class struggle, anti-fascist legitimacy, the leading role of the Communist Party and the supposed historical necessity of socialism. After 1989, historians were free to dismantle these interpretative frameworks, but the mere reversal of ideological signs would not have been sufficient. A democratic historiography had to ask different questions: how institutions actually functioned, how political culture changed, how social groups experienced transformation, how citizens adapted to pressure, how memory was constructed, and how the Czech and Slovak parts of the common state interacted. This change encouraged the development of political history, social history, cultural history, intellectual history, memory studies, oral history and the history of everyday life. Modern history became less a sequence of great dates and more an investigation of structures, practices and meanings.

The 19th century and the national movement remained indispensable for understanding the modern Czech project. The national revival had created not only literature and linguistic identity, but also a framework in which culture, politics and scholarship were closely intertwined. After 1989, historians could examine this period more critically, without simply reproducing revivalist mythology or socialist reinterpretations. The Czech nation could be studied as a historical construction formed through language, education, associations, print culture, political representation and competition within the Habsburg monarchy. This perspective did not weaken the significance of national revival. It made that significance more historically precise. The modern Czech nation appeared as a product of cultural labour, institutional imagination and social mobilisation, rather than as an ancient essence waiting to awaken (Macura, 1995; Sayer, 1998).

The First Czechoslovak Republic became another crucial object of reinterpretation. After 1989, it was often remembered as a democratic model and moral predecessor of the restored Czech democracy. This memory had strong foundations: the First Republic represented parliamentary democracy, cultural pluralism, educational expansion and international recognition. Yet historical research had to move beyond idealisation. It examined party politics, social inequality, nationality conflicts, Slovak autonomy, the position of Germans, Hungarians, Jews and Ruthenians, economic modernisation, agrarian politics, liberal institutions and the vulnerabilities of the state in the European crisis of the 1930s. The Republic could thus be appreciated without being mythologised. Its history became not only an object of nostalgic return, but a field for understanding the conditions under which democracy is built, strained and endangered (Agnew, 2004; Orzoff, 2009).

The Munich crisis of 1938 and the destruction of the First Republic remained among the most emotionally charged subjects of modern Czech history. Earlier interpretations had often used Munich as a symbol of betrayal, national vulnerability and Western failure. Post-1989 historiography did not discard these moral and political dimensions, but it placed them in wider diplomatic, military, social and Central European contexts. Historians could examine the international system, appeasement, Czechoslovak defence planning, minority politics, propaganda, public fear and the psychological shock of territorial dismemberment. Munich was no longer simply a national trauma repeated in commemorative language. It became an event through which scholars could analyse the fragility of small-state sovereignty, the crisis of interwar democracy and the transformation of European power before the Second World War.

The history of the Protectorate and the Second World War acquired a similarly expanded frame. Research after 1989 could address Nazi occupation, resistance, collaboration, repression, everyday survival, forced labour, cultural policy, the Holocaust and the relationship between Czech society and German power with greater archival and methodological freedom. The earlier anti-fascist narrative had preserved important elements of resistance memory, but it had often simplified the complexity of occupation society and underplayed the specificity of Jewish persecution. The post-1989 field became more attentive to local administration, social behaviour, moral ambiguity and the bureaucratic mechanisms of violence. It also situated Czech wartime experience within broader European histories of occupation, genocide and collaboration. This internationalisation was essential because the Protectorate was both a Czech national experience and part of Nazi Europe.

The post-war years between 1945 and 1948 emerged as one of the most difficult fields of interpretation. They were not merely a transition from war to communism, but a period of restoration, revenge, democratic hope, social radicalisation, ethnic transformation and growing dependence on the Soviet sphere. The expulsion and transfer of the German population, property confiscations, the National Front system, retributive justice, the reconstruction of political parties and the rising power of the Communist Party all required renewed study. Earlier official narratives had treated many of these developments as historically justified stages on the way to socialist renewal. Post-1989 historiography was able to ask more uncomfortable questions about violence, legality, national homogenisation and the moral costs of post-war state-building. The period became a key site for understanding how democratic language and authoritarian tendencies could coexist in the immediate aftermath of war (Frommer, 2005; Kopeček & Kolář, 2007).

The communist seizure of power in February 1948 and the Stalinist period became central to the new historiography of dictatorship. Historians could reconstruct political mechanisms, party strategy, security apparatuses, show trials, collectivisation, persecution of churches, restructuring of education, cultural control and the transformation of the economy. The study of Stalinism also forced historians to examine the social sources of communist power. The regime was not imposed only from above or from abroad; it also mobilised sections of society through promises of justice, advancement, national security and social equality. This did not diminish the violence of the dictatorship. It made the dictatorship historically intelligible as a system that combined coercion, ideology, opportunity and institutional transformation. Such research helped Czech society move beyond a simple image of communism as either foreign imposition or domestic destiny.

The 1960s and the Prague Spring became another major field of modern historical research. Under normalisation, the Prague Spring had been condemned or silenced; after 1989, it became available for detailed reconstruction. Historians examined reform communism, economic reform, the transformation of cultural life, debates inside the Communist Party, the role of intellectuals, the media, Slovak federalisation, civic participation and the international dimensions of the crisis. The Soviet-led invasion of August 1968 could then be studied not only as a military act but as the violent interruption of a complex reform process. This approach allowed historians to ask what kind of socialism the reformers imagined, what social forces supported them, and why the experiment was both promising and vulnerable. The Prague Spring thus became a subject of institutional, intellectual and social history rather than only a national symbol (Williams, 1997; Institute of Contemporary History of the CAS, n.d.).

Normalisation after 1969 demanded a different kind of historical imagination. It was not defined only by mass terror, although repression, purges, surveillance and exclusion were central to its operation. It also involved routine adaptation, career strategies, consumer aspirations, private retreat, cultural coding, selective compromise and the management of public language. Historians increasingly studied normalisation as a social order with its own forms of stability, fear and negotiation. This approach helped explain why the regime lasted for two decades after 1968 and why its collapse in 1989 was at once sudden and deeply prepared by long-term exhaustion. The study of normalisation also brought the history of everyday life into modern Czech historiography. It asked how people lived inside a regime that demanded loyalty but often received only ritual conformity (Bren, 2010; Vaněk & Mücke, 2016).

Dissent became one of the most prominent subjects of post-1989 research, but it also required careful contextualisation. Charter 77, samizdat, underground culture, religious activism, ecological initiatives and human rights networks were central to the moral history of late socialism. Yet scholarship had to avoid turning dissent into a simplified national conscience detached from social context. Historians examined the networks, internal disagreements, international contacts, philosophical language, legal arguments and everyday risks of dissent. They also asked why dissent remained socially limited, how it communicated with broader society and how it later influenced the political culture of the Velvet Revolution. This approach preserved the moral importance of dissent while transforming it into a serious historical field (Bolton, 2012; Kopeček, 2019).

The Velvet Revolution itself became an object of historical research almost immediately after it occurred. This presented a methodological challenge because historians were studying events that many of them had witnessed personally and that still shaped political legitimacy. Jiří Suk's detailed work on the revolutionary months from November 1989 to June 1990 showed how the fall of communist power involved negotiation, improvisation, symbolic action, institutional uncertainty and the interaction of civic movements with old state structures. Research on 1989 therefore moved beyond the image of a spontaneous moral uprising without political complexity. It examined Civic Forum, student mobilisation, party negotiations, security institutions, public demonstrations, media, federal politics and the emergence of new democratic elites. The revolution became history not by losing its emotional force, but by becoming available to source-based analysis (Suk, 2003; Judt, 2005).

The dissolution of Czechoslovakia in 1992–1993 opened another field of modern historical inquiry. The separation of the Czech Republic and the Slovak Republic was peaceful, but it raised profound questions about federalism, national identity, political representation,

constitutional design and the legacy of the common state. Historians and social scientists examined why a state that had survived occupation, communism and revolution did not continue after democratic renewal. The issue was not reducible to nationalist conflict. It involved party politics, economic reform, different visions of sovereignty, constitutional negotiation and the changing meaning of Czechoslovakism. Research on the dissolution helped place Czech history in relation to Slovak history rather than treating Slovak development as a secondary background to Czech statehood (Leff, 1997; Innes, 2001).

The post-1993 Czech Republic gradually became part of contemporary history as well. Historians began to study democratic consolidation, market transformation, restitution, privatisation, European integration, NATO accession, EU membership, constitutional culture, regional development and changing public memory. This field overlapped with political science, sociology and economics, but historical research added long perspective and archival sensitivity. It showed that post-socialist transformation was not only a technical transition from plan to market or dictatorship to democracy. It was also a struggle over memory, institutions, social expectations, expertise and national self-understanding. By extending contemporary history into the post-1989 period, the Academy helped prevent the present from appearing historically weightless.

Modern Czechoslovak history also required sustained attention to the Czech-Slovak relationship. For much of the 20th century, the Czech and Slovak histories were institutionally joined but socially and culturally distinct. The common state contained asymmetries of economic development, political influence, language, regional identity and historical memory. Under communism, federalisation after 1968 changed the constitutional structure but did not fully resolve deeper questions of equality and sovereignty. After 1989, these questions returned in democratic form. Historians therefore had to examine Czechoslovakia not only as a Czech national achievement but as a shared and contested political project. This was essential for avoiding a Prague-centred narrative of the common state.

The Academy's research on modern history also became increasingly comparative. Czech experience was placed alongside Polish, Hungarian, East German, Austrian, Slovak and broader Central European developments. This comparative perspective was crucial for studying nationalism, state socialism, post-war violence, dictatorship, dissent, transition and Europeanisation. It allowed historians to distinguish what was specific to the Czech lands from what belonged to wider regional patterns. It also helped Czech historiography enter international debates rather than remaining confined to national self-explanation. The Institute of Contemporary History's projects and public research profile reflect this outward orientation, especially in fields such as politics, institutions, power, democracy, everyday life in dictatorship and post-1989 transformation (Institute of Contemporary History of the CAS, n.d.; Institute of Contemporary History of the CAS, n.d.).

The history of institutions became especially important for the Academy's self-understanding. Modern Czech and Czechoslovak history is not only the history of parties, governments and revolutions. It is also the history of schools, universities, academies, courts, churches, cultural organisations, factories, trade unions, scientific institutes, archives and publishing houses. These institutions shaped the everyday experience of modernity and the practical operation of power. The archival fonds of the Czechoslovak Academy of Sciences and the Czech Academy of Sciences make it possible to study the scientific sector itself as part of modern history. The Academy therefore became both subject and object of historical research. Its historians could

examine how scholarly autonomy was created, restricted, defended and reformed across regimes (Masaryk Institute and Archives of the CAS, n.d.).

The role of oral history expanded the range of modern historical evidence. Many experiences of war, persecution, everyday socialism, dissent, exile and transition cannot be understood through official documents alone. Oral testimony captures memory, emotion, retrospective meaning and the language through which people narrate their lives. The Centre for Oral History, associated with the Institute of Contemporary History, contributed to the professionalisation of this field in the Czech context. Oral history was particularly important for studying ordinary people, marginalised groups and social experiences that state archives recorded only indirectly. It also made visible the tension between memory and documentation, which is central to modern historical research (Vaněk & Mücke, 2016; Digital Humanities Czech Academy of Sciences, n.d.).

Modern history research also had to deal with the public visibility of its findings. The subjects studied by historians of the 20th century were not emotionally neutral. They touched on family memory, property, political legitimacy, collaboration, victimhood, national pride and personal reputation. Historians were often expected to provide quick judgements, especially in debates about communism, the security services, lustration, collaboration or the expulsion of Germans. The Academy's role was to offer expertise without becoming a tribunal. This required a disciplined distinction between moral seriousness and prosecutorial simplification. Historical research could illuminate responsibility, but it had to do so through evidence, context and comparison.

The study of modern Czech and Czechoslovak history also transformed the concept of national memory. Earlier national narratives often privileged statehood, language, democratic tradition and resistance. Post-1989 research added occupation, minority experiences, post-war violence, dictatorship, exile, compromise, everyday life and the fragility of democratic institutions. This did not destroy national memory. It made it more adult. A democratic society does not need a flawless past; it needs a past it can examine without fear. The Academy's historians contributed to this maturation by replacing inherited certainties with documented complexity.

The disciplinary identity of modern history changed accordingly. It became less isolated from sociology, political science, anthropology, literary studies, law, economics and philosophy. The study of communism required knowledge of institutions, ideology, surveillance, social policy and everyday culture. The study of transition required attention to law, markets, political parties, elites and public discourse. The study of memory required concepts from cultural studies and psychology as well as archival skill. This interdisciplinary character did not weaken history as a discipline. It allowed historians to treat modern society as a complex historical organism rather than a sequence of political events.

The research agenda of the Institute of Contemporary History demonstrates this development. Its focus on politics, institutions and power includes the Communist Party, the Prague Spring, parliamentarianism, security services, armed forces and political transformation after 1989. Such themes show how contemporary history bridges dictatorship and democracy, institutional continuity and change, national development and Europeanisation. They also show why the Academy's study of modern history cannot be reduced to memory politics. It is a systematic investigation of power, social processes and institutional practices from the late

interwar crisis to the contemporary Czech state (Institute of Contemporary History of the CAS, n.d.).

The modern history of the Czech lands also remains inseparable from European integration. The post-1989 return to Europe was not only a diplomatic slogan but a historiographical problem. It required scholars to reconsider Czech history within the broader history of Central Europe, empire, democracy, fascism, communism and European institutions. Research on EU accession and Europeanisation connected contemporary Czech history with questions of sovereignty, law, identity and policy transfer. At the same time, historical scholarship could challenge simplified claims that Czech history had simply "returned" to a natural Western path after 1989. The Czech lands had always been European, but their European history was marked by imperial structures, borderlands, occupation, ideological division and post-socialist transformation.

In the longer view, research on modern Czech and Czechoslovak history after 1989 helped redefine the Academy's public role. The Academy was no longer merely a centralised research body inherited from the socialist system. It became an autonomous institution capable of examining the very historical conditions that had shaped it. In modern history, this meant asking difficult questions about the relationship between scholarship and power, between memory and evidence, and between national culture and democratic critique. The Academy's historians did not produce a final narrative of the Czech 20th century. They created the conditions for an open, source-based and plural understanding of it.

Thus, research on modern Czech and Czechoslovak history became one of the decisive humanities fields in the post-1989 Czech Academy of Sciences. It reconstructed the modern past from the national movement and the First Republic through occupation, communism, the Prague Spring, normalisation, dissent, revolution, state dissolution and democratic transformation. It developed new institutional centres, especially the Institute of Contemporary History, while drawing on the broader capacities of the Institute of History and the Masaryk Institute and Archives. Its importance lay not only in correcting earlier ideological distortions, but in changing the very questions historians asked: how institutions function, how societies remember, how democracy survives, how dictatorship becomes ordinary, and how national identity is formed through conflict as well as continuity. In this sense, modern historical research became a central mechanism through which Czech society learned to interpret its recent past without surrendering either to myth or to amnesia.

2. Totalitarianism, Democracy, and Collective Memory

The relationship between totalitarianism, democracy and collective memory became one of the most difficult and revealing themes in Czech humanities research after 1989. The end of communist rule did not simply remove an authoritarian regime from political life; it also released a long conflict over the meaning of the 20th century. Czech society had to confront Nazi occupation, communist dictatorship, Stalinist violence, post-war ethnic transformation, the Prague Spring, normalisation, dissent and the negotiated character of the Velvet Revolution. These were not only historical topics but moral and political resources through which new democratic identities were formed. The Academy's historians entered this field at a moment when society wanted clarity, but the documents, memories and institutional continuities often pointed towards ambiguity. Their task was therefore not to weaken the moral

distinction between dictatorship and democracy, but to prevent that distinction from becoming an excuse for simplified history (Kopeček & Kolář, 2007; Bren, 2010; Suk, 2003).

The concept of totalitarianism had particular force in the Czech post-1989 environment because it offered a language for rejecting both Nazism and communism as systems of anti-democratic power. It named not only repression but the ambition of a regime to dominate public institutions, political language, collective memory, social organisations and individual behaviour. Yet for historians the term also required caution. If used too broadly, it could flatten the historical differences between Nazi occupation, Stalinist terror, late-socialist normalisation and the bureaucratic authoritarianism of the 1970s and 1980s. If used too narrowly, it could fail to capture the structural violence and ideological ambition of communist rule. Czech scholarship therefore had to work with "totalitarianism" as both a political memory term and an analytical problem. It could not simply adopt the concept as a slogan, but neither could it ignore its place in democratic self-definition (Arendt, 1951/1973; Gleason, 1995; Institute for the Study of Totalitarian Regimes, n.d.).

The founding of the Institute of Contemporary History in 1990 created a professional academic space for this difficult work. The institute was established to conduct independent research into Czech and Czechoslovak history after 1938, precisely the period in which democracy, dictatorship, occupation and state socialism collided most violently. Its role differed from that of commemorative institutions or political bodies. It did not exist to pronounce official moral verdicts, although its research inevitably entered public debates about responsibility, victimhood and democratic identity. Rather, it was expected to investigate the structures and experiences of recent history through archives, oral testimony, comparative methods and public scholarship. This gave the Academy a distinctive position in the field of memory: it was close enough to society to understand the urgency of the past, but institutionally committed to scholarly autonomy and critical distance (Institute of Contemporary History of the CAS, n.d.; Digital Humanities Czech Academy of Sciences, n.d.).

Collective memory differs from professional history, although the two constantly interact. Memory is selective, affective, identity-forming and often transmitted through families, schools, anniversaries, monuments, films, museums and political rhetoric. History is also shaped by values and questions, but it is disciplined by source criticism, contextualisation, argument and revision. After 1989, Czech democracy needed both memory and history. Memory gave moral urgency to the rejection of dictatorship; history prevented memory from hardening into myth. The Academy's contribution lay precisely in mediating between these two modes of relating to the past. It could not replace public memory, but it could examine how memory was formed, used, contested and sometimes manipulated (Halbwachs, 1950/1992; Assmann, 2011; Verovšek, 2016).

The memory of Nazi occupation occupied a special place in this field because it predated communist rule and had been incorporated into socialist legitimacy after 1948. Communist historical narratives frequently presented the regime as the culmination of anti-fascist struggle, thereby turning the memory of resistance into a source of party authority. After 1989, historians had to disentangle the real history of occupation, resistance and persecution from its later instrumentalisation. This meant studying the Protectorate, collaboration, everyday survival, the Holocaust, forced labour, repression and local institutions without allowing anti-fascist memory to remain the property of any single political tradition. Democratic historiography had to preserve the moral clarity of anti-Nazi resistance while also examining

the social complexity of occupation society. The result was a broader understanding of totalitarian violence as both an external occupation regime and a field of local choices, constraints and responsibilities.

The communist period created a different memory problem because many of its actors, victims, beneficiaries and bystanders remained present in post-1989 society. Unlike the Nazi occupation, communist rule had not ended with military defeat and external liberation. It ended through a negotiated revolutionary process in which old institutions, former party members, dissidents, experts and pragmatic reformers all participated in the transition. This made collective memory politically delicate. The new democracy rejected the communist monopoly of power, but it also inherited personnel, buildings, archives, habits and social expectations from the previous system. Historians therefore had to examine dictatorship not as an alien layer simply removed in 1989, but as a social order that had entered institutions, careers, language and everyday life (Suk, 2003; Judt, 2005).

Stalinism was the clearest case of totalitarian violence in Czechoslovak communism. Political trials, executions, imprisonment, forced labour camps, collectivisation, church persecution, ideological campaigns and the restructuring of education and culture revealed the regime's aspiration to remake society through fear and mobilisation. After 1989, archival access allowed historians to reconstruct the mechanisms of repression and the social worlds of victims, perpetrators and institutions. Yet even here, research had to go beyond the catalogue of crimes. It had to ask how violence was legitimised, how party cadres understood their mission, how ordinary citizens responded, and how social advancement and coercion interacted. The history of Stalinism thus became not only a moral indictment but an inquiry into the mechanisms through which a political project becomes a system of domination.

The Prague Spring complicated the memory of communism because it showed that the communist movement had contained reformist energies as well as authoritarian structures. For many Czechs and Slovaks, 1968 remained a memory of hope, public debate, cultural liberation and the possibility of "socialism with a human face". For others, it was evidence that communism could not reform itself without collapsing under Soviet pressure. After 1989, historians had to study the Prague Spring without reducing it either to democratic anticipation or to communist illusion. The movement involved reform politicians, economists, writers, journalists, students, Slovak federalists and citizens who imagined different futures. Its defeat by invasion and subsequent normalisation created one of the deepest fractures in modern Czech memory (Williams, 1997; Bren, 2010).

Normalisation after 1969 was especially challenging for collective memory because its violence was often quieter than that of Stalinism. It relied on purges, surveillance, career exclusion, censorship, ritual loyalty, professional pressure and the management of social conformity. Many people did not experience it as spectacular terror but as a world of compromises, silences and limited private freedoms. This made moral judgement both necessary and difficult. A society could not simply classify everyone as victim, collaborator or opponent. Historians of normalisation therefore explored grey zones: the everyday practices through which people adapted to power, preserved private dignity, benefited from the system or withdrew from public life. This scholarship helped Czech society understand dictatorship as a structure of ordinary life, not only as a series of dramatic acts of repression (Bren, 2010; Vaněk & Mücke, 2016).

The study of dissent played a central role in the democratic memory of late socialism. Charter 77, underground culture, samizdat, religious opposition, ecological activism and human rights initiatives became symbols of civic courage. Yet professional history had to preserve dissent from becoming a simple legend. Dissent was morally important, but socially limited; it contained different ideological tendencies, personal tensions and strategic disagreements; it depended on international attention, informal networks and the language of law and responsibility. Research on dissent therefore deepened democratic memory by showing how difficult, fragile and often lonely civic resistance could be. It also prevented the post-1989 public from imagining that the whole nation had been dissident in retrospect (Bolton, 2012; Kopeček, 2019).

Collective memory after 1989 was strongly shaped by the question of victimhood. Victims of Nazism, political prisoners of communism, persecuted clergy, expelled Germans, collectivised farmers, dismissed scholars, surveilled dissidents, Roma communities, Jewish survivors and many others could claim recognition from the democratic public sphere. These claims were not identical and sometimes conflicted. Some memories had long been publicly honoured; others had been suppressed; still others remained socially uncomfortable. Historians had to resist competitive victimhood while acknowledging real suffering. The Academy's research could help by placing each group's experience into documented historical contexts rather than into a hierarchy of moral visibility. Such work was essential for a plural democratic memory.

The politics of memory became more visible as the Czech Republic consolidated democracy and entered Euro-Atlantic institutions. Public debates about lustration, security archives, communist symbols, school teaching, monuments, anniversaries and the legal status of the communist regime all showed that memory was a political language. Different parties and civic groups used the past to define patriotism, responsibility and democratic legitimacy. Scholars could not pretend that their work existed outside these debates. Yet they had to maintain a difference between political use of history and historical research. This distinction was not a retreat from public life; it was the condition of meaningful public expertise (Kopeček & Kolář, 2007; Činátl, 2013).

The creation of the Institute for the Study of Totalitarian Regimes and the Security Services Archive in 2007 institutionalised a state-supported memory agenda outside the Academy. The relevant law defined tasks connected with the study and documentation of the Nazi period and the period of communist totalitarian power, including the activities of security services, persecution and resistance. This development demonstrated that memory of dictatorship had become a matter of public policy. It also created a new institutional environment in which Academy historians worked alongside, and sometimes in critical relation to, official memory institutions. The distinction mattered. A state memory institute may have a legal mandate to document totalitarian regimes, while an Academy institute must preserve the broader academic logic of inquiry, comparison and debate (Act No. 181/2007 Coll., 2007; Institute for the Study of Totalitarian Regimes, n.d.).

Security-service archives played a decisive role in this memory landscape. Files of the State Security and related organs seemed to offer direct access to hidden structures of power, collaboration and surveillance. Yet historians had to approach them critically because they were produced by institutions of control. Reports could contain distortions, ambitions, misunderstandings, fabricated claims or bureaucratic self-justification. A person's presence

in a file did not automatically explain motive, degree of agency or moral responsibility. The Academy's historical method was therefore indispensable for preventing the archive from becoming a substitute for judgement. The documentary record of repression had to be read both as evidence and as a product of repressive power.

Lustration intensified the tension between archive, democracy and memory. The new democratic state sought to protect public institutions from certain forms of continuity with the communist security and party apparatus. This was a legitimate problem for a post-authoritarian democracy, but its practical implementation relied on documents created by the previous regime. The paradox was obvious: democracy used the paperwork of dictatorship to define public trust. Historians did not control lustration policy, but their work helped society understand its assumptions, limits and consequences. The scholarly reading of files introduced complexity into a public field that often demanded simple exposure (David, 2003; Williams, 2003).

Oral history added another dimension to collective memory. The experiences of dictatorship, occupation, persecution and transition are not preserved only in official documents. They also live in voices, gestures, silences, family stories and retrospective narratives. The development of oral history in the Czech Republic after 1989 helped capture experiences that archives often recorded only indirectly or through the language of institutions. The Centre for Oral History associated with the Institute of Contemporary History contributed to the professionalisation of this method. Oral testimony did not replace documents; it complicated them. It made clear that memory is not a defect of history but one of its sources, provided it is interpreted critically (Vaněk & Mücke, 2016; Mücke, 2017).

The broader Czech memory environment also included civic projects such as Memory of Nations, which collected testimonies of people who lived through 20th-century totalitarian regimes. Such projects enlarged the public archive of memory and made personal narratives accessible to schools, journalists and citizens. The Academy's role was different but complementary. It could use oral testimony within broader research designs, compare it with archival evidence, and interpret it through social and political history. This relationship between civic memory and academic history is one of the defining features of post-1989 Czech historical culture. Public testimony gives history emotional immediacy; scholarly analysis gives it structure and context.

Democracy itself became an object of memory. The First Republic, the Prague Spring and the Velvet Revolution all served as reference points for democratic identity, but each carried different meanings. The First Republic represented parliamentary statehood and international recognition; the Prague Spring represented reform, participation and interrupted hope; the Velvet Revolution represented civic mobilisation and peaceful transition. Yet none of these memories could be treated as a perfect democratic model. The First Republic had nationality conflicts and social tensions, the Prague Spring remained inside a socialist horizon, and the Velvet Revolution involved negotiation with the old regime. Historical scholarship helped democracy remember its own traditions without turning them into legends (Orzoff, 2009; Suk, 2003).

The memory of the expulsion of Germans after the Second World War remained one of the most difficult issues in Czech collective memory. For decades it had been framed primarily as the outcome of Nazi aggression and the restoration of national justice. After 1989, historians could more openly examine violence, property confiscation, administrative procedures,

international agreements and the transformation of borderlands. This did not mean ignoring the trauma of Munich, occupation and Nazi crimes. It meant recognising that victimhood in one historical context does not remove moral questions in another. The study of the expulsion therefore became a test of democratic memory's maturity: could Czech society examine suffering caused by Czechs without abandoning the memory of suffering endured by Czechs? (Frommer, 2005; Kopeček & Kolář, 2007).

The Holocaust also required renewed attention within Czech memory. Communist narratives had often absorbed Jewish suffering into general anti-fascist martyrdom, thereby obscuring the specificity of genocide. After 1989, historians, museums, schools and cultural institutions increasingly addressed the Jewish history of the Czech lands, the Protectorate, deportations, property confiscation, survivor memory and post-war restitution. This work connected Czech history to broader European and global Holocaust studies. It also challenged national narratives that had treated the wartime past mainly through Czech resistance and suffering. The democratic memory of the Holocaust required both empathy and precise historical reconstruction.

The memory of Roma communities posed another challenge. Roma experiences of persecution, social exclusion, forced assimilation, labour camps, sterilisation practices, post-war marginalisation and contemporary discrimination were often peripheral in national historical narratives. The inclusion of Romani histories in contemporary research signalled a widening of collective memory beyond dominant national groups. It also showed that democracy requires attention to those whose memories have been structurally neglected. The Institute of Contemporary History's research profile, including Romani histories and marginalised groups, reflects this broader turn. In this context, collective memory becomes not only a story of state and nation but a field of social justice and historical visibility.

The study of collective memory also required attention to education. School textbooks, curricula and teachers transmit historical narratives to new generations, often long after scholarly debates have changed. After 1989, Czech schools had to teach communism, occupation, the Holocaust, the First Republic, 1968 and 1989 in a society where parents and grandparents carried different memories. This made history education a crucial site of democratic formation. Academic historians could contribute by producing reliable research, participating in public debate, advising educational projects and warning against ideological simplification. The classroom became one of the places where the distinction between memory and history mattered most.

Museums, monuments and anniversaries formed another arena of collective memory. Public commemoration often requires condensed symbols, while historical scholarship works through complexity. Anniversaries of 1918, 1938, 1948, 1968 and 1989 repeatedly brought historians into public discussion. The Academy's role was not to deprive commemoration of emotion, but to enrich it with context. A commemorative culture without scholarship becomes ritualised; scholarship without public memory becomes socially thin. The strongest democratic memory emerges when these two forms of engagement correct one another.

The digital age transformed collective memory by multiplying access to documents, photographs, testimonies, databases and digitised publications. Digital archives allow citizens and researchers to encounter the past outside traditional reading rooms. They also create new dangers: decontextualised documents, viral fragments, politicised images and algorithmic selection can intensify memory conflicts. The Academy's digital humanities infrastructure

therefore has a memory function as well as a technical function. It helps create reliable, curated and citable resources in an environment where historical fragments circulate rapidly and often without context. Digital access strengthens democracy only when it is accompanied by critical literacy.

The concept of collective memory also helped Czech historians move beyond institutional history alone. It allowed them to ask how societies remember, forget, commemorate, silence and reinterpret. Memory studies brought together history, sociology, anthropology, political science, literary studies and psychology. This interdisciplinary character suited the Academy's broader humanities structure. It made possible research on commemorative practices, public discourse, political uses of the past, family memory, oral testimony, cultural representation and the symbolic geography of monuments. Modern history became inseparable from the study of how modern history is remembered.

At the same time, historians had to defend the specificity of their discipline within memory studies. Not every memory is historically accurate, and not every emotionally powerful narrative is a reliable account of the past. The historian's task is not to humiliate memory but to test it, contextualise it and understand its formation. This is especially important in societies emerging from dictatorship, where memories may carry trauma, shame, self-justification or political expectation. The Academy's expertise consisted in treating memory as evidence, not as a substitute for evidence. This distinction helped preserve the integrity of historical research.

The tension between democracy and memory also appears in the problem of nostalgia. Some citizens remembered late socialism not primarily through repression but through employment security, social predictability, housing, childhood, family life or cultural consumption. Such nostalgia could irritate anti-communist memory, but historians had to study it seriously. Nostalgia does not prove that dictatorship was benign; it reveals how people remember their own lives inside political systems. Research on everyday life helps explain why memories of communism are often ambivalent, especially across generations. A democratic society gains depth when it can understand such ambivalence without allowing it to excuse authoritarian power.

The Academy's historians also contributed to the Europeanisation of Czech memory. The memory of communism became part of broader European debates about totalitarianism, human rights, transitional justice and the moral geography of the 20th century. Czech scholars participated in comparative discussions about East Central Europe, Soviet domination, dictatorship, resistance and post-communist transformation. This European context was important because Czech memory could not remain purely national. Nazism and communism were transnational systems, and their remembrance became part of European political culture. At the same time, Czech historians had to ensure that European memory frameworks did not erase local specificity.

The relationship between totalitarianism and democracy therefore remained dynamic rather than settled. Democracy defined itself partly through the rejection of totalitarian rule, but it also had to confront its own limitations, exclusions and inherited structures. The study of the past became a way of testing democratic maturity. Could the new society examine collaboration without vengeance, victimhood without competition, resistance without mythology, and dictatorship without nostalgia? Could it recognise that democracy is not guaranteed by

memory alone, but requires institutions, critical education, public debate and legal culture? The Academy's humanities helped articulate these questions with historical precision.

The importance of collective memory was also visible inside the Academy itself. The Academy inherited institutes, archives and personnel from the Czechoslovak Academy of Sciences, which had operated within the socialist system. Its post-1989 self-definition therefore required institutional memory as well as national memory. Historians could study purges after 1968, ideological control, scholarly adaptation, international isolation, research excellence and reform after the Velvet Revolution. This internal memory prevented the Academy from presenting itself only as a guardian of society's past. It also made the Academy a subject of historical accountability.

The study of totalitarianism, democracy and collective memory thus placed the Academy at the centre of a broader democratic conversation. Its historians did not have the final word on public memory, and they did not control political uses of the past. Yet they provided disciplined knowledge in a field where emotional and political pressures were intense. Their work helped distinguish between evidence and accusation, between commemoration and explanation, between moral judgement and historical simplification. In this respect, the Academy's role was not merely academic. It was civic, because democracy depends on the ability to argue about the past without surrendering either to amnesia or to propaganda.

Thus, research on totalitarianism, democracy and collective memory became a defining part of the Czech Academy of Sciences' humanities mission after 1989. It connected the study of Nazi occupation, communist dictatorship, Stalinism, the Prague Spring, normalisation, dissent, revolution and post-socialist transformation with broader questions of public memory and democratic identity. The Academy's contribution lay in maintaining scholarly autonomy within a highly politicised memory landscape. It did not deny society's need for moral clarity, but it insisted that moral clarity must be supported by evidence, context and methodological discipline. By doing so, Czech contemporary history helped transform the rejection of totalitarian rule from a political declaration into a sustained culture of democratic historical reflection.

3. The Social Role of Historical Expertise

The social role of historical expertise after 1989 became one of the most important dimensions of the Czech Academy of Sciences' humanities mission. In a democratic society emerging from dictatorship, historians were not asked only to produce monographs, archival editions or specialist articles. They were also expected to help society understand what had happened, why it had happened, who had been responsible, how institutions had functioned and how the past should be remembered without becoming a new instrument of political simplification. This placed historical expertise in a difficult position between scholarship and public demand. The public often wanted clarity, moral judgement and accessible narratives, while professional history required source criticism, contextualisation and awareness of ambiguity. The Academy's historians therefore had to develop a form of public authority different from the authority claimed by ideological historiography under state socialism. Their authority had to rest not on political loyalty, but on method, evidence, transparency and the willingness to revise interpretations when sources demanded it (*Kopeček & Kolář, 2007*; *Suk, 2003*).

The first social function of historical expertise was corrective. After decades of ideological selection, censorship and official memory, Czech society needed reliable knowledge about events, institutions and persons that had been distorted or silenced. Historians helped reconstruct the history of political trials, forced collectivisation, persecution of churches, post-war violence, the security services, exile, samizdat, dissent, normalisation and the Velvet Revolution. This corrective role was necessary, but it was also dangerous if reduced to exposure alone. A democratic public sphere cannot live permanently in the mode of revelation, scandal and denunciation. Historical expertise had to move from uncovering hidden facts towards explaining structures, motives, contexts and consequences. In this sense, the social role of historians was not only to say what had been concealed, but to show how a society could understand concealed facts without turning them into another mythology.

The Institute of Contemporary History became a central institution for this public function. Founded in 1990, it developed as a workplace of the Czech Academy of Sciences devoted to contemporary Czech and Czechoslovak history from 1938 to the present in an international context. Its research agenda included political institutions, power structures, the Communist Party, the Prague Spring, security services, parliamentarianism, social transformation and post-1989 democracy. Such topics were inherently public because they concerned the moral and institutional biography of the modern Czech state. The institute's formulation "To know the past, to understand the present" captures the social logic of this work. Historical expertise was not presented as antiquarian knowledge, but as a means of interpreting the present through disciplined investigation of the recent past (*Institute of Contemporary History of the CAS, n.d.*; *Institute of Contemporary History of the CAS, n.d.*).

The Academy's mission as a whole supported this public orientation. The Czech Academy of Sciences defines its work as research across the natural, technical and social sciences and the humanities, while taking into account the needs of Czech society and national culture. This formulation is particularly significant for historical research. The "needs of society" in history are not identical with political convenience or public comfort. They include the need for accurate knowledge, critical memory, institutional self-understanding, cultural continuity and the ability to discuss difficult subjects without manipulation. Historians therefore serve society best when they do not simply confirm what society already wants to hear. Their public usefulness often lies in complicating inherited assumptions (*Academy of Sciences of the Czech Republic, n.d.*).

Historical expertise after 1989 also became essential for transitional justice. Lustration, rehabilitation, restitution, court cases, access to security files and the public evaluation of communist officials all required some relationship to the documentary past. Historians were not judges, prosecutors or legislators, but their work informed the wider moral and evidentiary environment in which such decisions were made. They clarified institutional contexts, explained the structure of the Communist Party and security apparatus, reconstructed mechanisms of coercion and warned against naïve readings of repressive archives. This role required care because historical interpretation could affect reputations, legal claims and public trust. The historian's task was not to replace legal procedure, but to provide the contextual intelligence without which legal and political decisions risk becoming crude or symbolic (*David, 2003*; *Williams, 2003*).

The opening of security-service archives made this role especially visible. Public debate often treated files of the State Security as if they offered direct access to truth. Historians had to

explain that such documents were produced by institutions of surveillance and control, and therefore carried the categories, ambitions and distortions of those institutions. A file could reveal contact, observation or pressure, but it could not by itself explain conscience, intention or degree of agency. Historical expertise was needed to distinguish evidence from bureaucratic inscription. This did not relativise collaboration or repression. It made the study of collaboration and repression more accurate by refusing to adopt the secret police's language as the final language of democratic judgement.

The second social function of historical expertise was educational. Post-1989 schools faced the difficult task of teaching a past that parents and grandparents had experienced differently and remembered emotionally. The history of communism, the Prague Spring, normalisation, dissent and 1989 could not be taught as distant material. It entered classrooms through family stories, political opinions, media debates and commemorative rituals. Academic historians contributed by producing research, textbooks, public lectures, documentary resources and interpretative frameworks that could help teachers avoid both nostalgia and simplistic anti-communist catechism. Historical education in a democracy requires more than a list of crimes and anniversaries. It requires students to understand how institutions, ideologies and social practices make dictatorship possible, and how democratic culture depends on critical memory.

The public role of historians was also connected with anniversaries. Dates such as 1918, 1938, 1945, 1948, 1968, 1969, 1977, 1989 and 1993 repeatedly brought historians into media, museums, schools and public ceremonies. Anniversaries have emotional and symbolic power, but they also risk compressing historical complexity into slogans. The Academy's historians could use anniversaries as opportunities for public education rather than ritual repetition. They could explain the First Republic without mythologising it, Munich without reducing Czech history to betrayal, 1945 without ignoring post-war violence, 1968 without romanticising reform communism, and 1989 without overlooking negotiation and institutional continuity. In this way, historical expertise helped transform commemoration into reflection.

Museums and exhibitions formed another arena in which historical expertise entered social life. Exhibitions on occupation, communism, exile, everyday life, scientific institutions or the Velvet Revolution require narrative choices, selection of objects, captions, chronology, visual interpretation and ethical framing. Historians contribute not only facts but judgement about representation. They help determine what should be shown, how documents should be contextualised and how visitors should encounter traumatic or controversial material. This is especially important in histories of violence and repression, where aesthetic presentation can easily become sensational or sentimental. Professional expertise helps museums preserve seriousness without becoming inaccessible.

The media environment after 1989 created new opportunities and pressures. Historians appeared in newspapers, television, radio, documentaries, podcasts and online platforms. This broadened the reach of academic knowledge, but it also demanded compression, clarity and sometimes conflict. Media formats often privilege direct answers, strong statements and personalised dispute. Historical scholarship, by contrast, proceeds through qualification, evidence and slow accumulation. Academy historians therefore had to learn how to speak publicly without abandoning the complexity of their work. The social role of expertise in the media is not to turn historians into commentators on every political quarrel. It is to provide historically grounded orientation when the past is invoked in public argument.

Digital communication intensified this challenge. Online archives, databases, digitised periodicals and documentary portals made historical materials accessible to a much wider public. At the same time, decontextualised images, isolated documents, conspiracy narratives and politically motivated fragments circulated more quickly than scholarly interpretation. Historical expertise in the digital age therefore includes curation, explanation and source literacy. The Academy's digital humanities resources, library collections and research databases contribute to this civic infrastructure. They provide reliable points of access in a public sphere where historical information is abundant but not always trustworthy. The historian's role becomes partly that of a guide through documentary excess.

The social role of historical expertise also involves protecting society from the misuse of analogy. Public debates often compare contemporary political conflicts with Munich, 1948, normalisation or 1989. Such analogies can illuminate patterns, but they can also distort present choices by forcing them into emotionally loaded historical scripts. Historians are useful precisely because they can show where analogies work and where they fail. They can explain that every present crisis has historical echoes but also specific causes, actors and institutions. This is a modest but crucial democratic service. It prevents history from becoming a warehouse of rhetorical weapons.

Expertise in modern history also contributes to policy debates, although not in the same way as economics or public administration. Historians can clarify the long-term effects of institutional reforms, centralisation, regional inequality, minority policy, education, security structures and state-society relations. They can show how past decisions shaped present administrative habits and public expectations. In the Czech case, the history of federalism, local government, national minorities, property relations, scientific institutions and public administration remains relevant to contemporary governance. Historical expertise does not produce technical policy formulas. It provides temporal depth, reminding decision-makers that institutions carry memory and that reforms act upon inherited structures.

The Academy's historians also serve society by preserving institutional memory. Modern states and public institutions often prefer simplified narratives of their own development. The archives of the Czechoslovak Academy of Sciences, the Czech Academy of Sciences and other scholarly bodies allow historians to reconstruct how scientific institutions functioned under different regimes. This includes research achievements, international cooperation, ideological pressure, purges, personnel decisions, reforms and adaptation. Such work matters because institutions without critical memory easily become celebratory or defensive. Historical expertise helps the Academy and other institutions understand themselves as historical actors rather than timeless administrative entities (*Masaryk Institute and Archives of the CAS, n.d.*).

The history of science is especially important in this regard. The Academy's own past includes learned societies, national scholarly institutions, the Czechoslovak Academy of Sciences, political control after 1948, normalisation after 1968, the transformation after 1989 and modern public research governance. Historians of science can examine how knowledge was produced under changing political, financial and ideological conditions. They can ask how researchers protected autonomy, how disciplines were reorganised, how international contacts were managed and how scientific authority was linked to the state. This research has a social function because it shows that science itself is historically situated. It also protects science from the false image of complete separation from society.

Historical expertise also contributes to local and regional memory. National history is often narrated from Prague and through central institutions, but Czech society is made of regions, towns, borderlands, industrial zones, villages and local communities with different experiences. The history of the Sudeten borderlands, Moravia, Silesia, industrial Ostrava, rural collectivisation, regional dialects, local resistance and local post-war violence all require grounded historical work. Academy historians may not replace local historians, but they can provide methods, comparative frameworks and scholarly infrastructure. Regional history is socially important because it allows citizens to see their own places within wider historical processes.

The role of oral history expanded the democratic reach of historical expertise. Oral history brought the voices of witnesses, workers, dissidents, former party members, prisoners, women, migrants, Roma, regional actors and ordinary citizens into the research field. It allowed historians to study not only what institutions recorded, but how people remembered, narrated and interpreted their own lives. The Institute of Contemporary History and its associated oral history work helped professionalise this field in the Czech context. Oral history also has a strong public function because it gives citizens a sense that their lives are part of history. Yet the historian must still interpret testimony critically, comparing memory with documents and social context (*Vaněk & Mücke, 2016*; *Mücke, 2017*).

Historical expertise is also important in confronting nostalgia. Memories of state socialism are not uniform. Some people remember repression, surveillance and fear; others remember youth, employment stability, social security, housing, popular culture or family life. Historians must be able to explain this plurality without converting it into either apology or condemnation. Nostalgia can reveal social disappointment in the present, generational difference or the selective nature of memory. It does not prove that dictatorship was acceptable. Historical expertise allows society to understand why authoritarian pasts can be remembered ambivalently and why democratic memory cannot be built only on moral instruction (*Bren, 2010*; *Kopeček, 2008*).

The social role of historical expertise also includes giving language to victims without reducing them to victimhood. Political prisoners, persecuted clergy, Holocaust survivors, collectivised farmers, expelled populations, dissidents, surveilled citizens and marginalised communities all require recognition. Yet historical research must also preserve their agency, social context and individuality. Victims are not only symbols of suffering; they are historical actors with biographies, choices, relationships and voices. The Academy's historical work can help prevent public memory from turning suffering into abstraction. It can also show that recognition of one group's suffering need not erase another's.

The public use of history is particularly sensitive where Czech memory intersects with German, Jewish, Slovak, Roma and broader Central European histories. Historical expertise helps society avoid a narrow national self-image. The expulsion of Germans, the Holocaust, Czech-Slovak relations, minority policies and borderland transformations all require research that crosses linguistic, archival and national boundaries. This is one of the Academy's important social functions: it connects Czech public memory with European historical scholarship. A mature national memory does not fear comparison. It becomes stronger when it can situate itself within wider histories of violence, democracy, migration, nationalism and state-building.

Historical expertise also supports democratic resilience. Authoritarian politics often manipulates history by creating myths of betrayal, purity, decline or national humiliation.

Democratic societies require citizens capable of recognising such manipulation. Historians contribute by showing that the past is complex, that institutions matter, that freedoms are fragile and that political language has consequences. This role is not party-political in the narrow sense. It is civic. Historical knowledge helps citizens understand how democratic institutions can be weakened, how conformity can become ordinary and how public truth can be eroded.

The Academy's historians must nevertheless avoid becoming moral instructors detached from scholarship. Their credibility depends on research, not on virtue signalling. The more publicly sensitive the topic, the more important it is that historians show their sources, methods and uncertainties. Expertise cannot demand trust while hiding its procedures. In post-1989 Czech society, where official truth had been discredited, this transparency was especially important. Historical authority had to be rebuilt through openness rather than command.

The relationship between historians and the state therefore remains delicate. Public institutions may fund research, request expertise, support commemorations or create memory laws. Historians can cooperate with the state, but they must not become its narrative service. The Academy's autonomy is crucial here. Because it is a public research institution rather than a ministry, court or political party, it can provide expertise while retaining critical distance. This allows it to serve society without simply serving power. The distinction is one of the foundations of democratic historical culture.

The social role of historical expertise also includes international communication. Czech modern history is not always well understood abroad, and simplified images of Czechoslovakia, communism, 1968 or 1989 often circulate internationally. Academy historians contribute to international scholarship by publishing in foreign languages, participating in comparative projects and translating Czech questions into broader European debates. This internationalisation has a public function at home as well. It prevents national history from becoming provincial and allows Czech society to see its own experience in relation to other histories of dictatorship, democracy and transformation.

At the same time, historians must translate international concepts carefully into Czech contexts. Terms such as totalitarianism, transitional justice, civil society, memory politics, everyday life, post-socialism and populism can illuminate Czech history, but they can also obscure local specificity if applied mechanically. Historical expertise requires conceptual mediation. Academy researchers are well placed for this because they work between domestic archives and international debates. Their social role includes protecting Czech history both from national isolation and from careless theoretical importation.

The Academy's historical expertise also contributes to the long-term preservation of evidence. Public debates may focus on interpretation, but interpretation depends on archival survival, cataloguing, digitisation, editions and bibliographies. The social function of history therefore begins before any public lecture or media comment. It begins with conserving documents, organising collections, preparing source editions and maintaining databases. This infrastructure allows future citizens and scholars to ask questions that the present may not yet know how to formulate. In this sense, historical expertise serves society across generations.

The COVID-19 period showed, in another way, that contemporary history is not only about distant political regimes. Historians and oral historians began documenting social experiences of crisis, public health measures, institutional responses and everyday uncertainty. This demonstrated that the Academy's historical expertise can respond to current events without

becoming journalism. Contemporary history begins when society recognises that the present is already producing archives, memories and future questions. The historian's task is to preserve and interpret these traces before they disappear. This expands the social meaning of historical expertise beyond commemoration of established pasts.

Historical expertise also affects the ethics of public speech. Historians know that words such as "fascism", "communism", "occupation", "collaboration", "resistance", "genocide", "revolution" and "normalisation" carry heavy historical meanings. When used carelessly, they flatten public discourse. The historian's contribution is partly semantic: to clarify what these terms meant in particular contexts and what they can responsibly mean today. This is another link between historical expertise and democratic culture. A society that uses historical terms carelessly becomes vulnerable to emotional manipulation.

The social role of historians is therefore not reducible to popularisation, although popularisation is important. It includes education, archival stewardship, public consultation, institutional memory, media explanation, civic warning, international comparison, conceptual clarification and ethical contextualisation. The Academy's historians operate in a space where research and public life meet, but they must preserve the difference between them. Their public speech is valuable because it comes from scholarly discipline. If that discipline is abandoned, expertise becomes opinion; if public communication is abandoned, expertise becomes socially isolated.

Thus, the social role of historical expertise in the Czech Academy of Sciences after 1989 lay in transforming historical knowledge into a democratic public resource without reducing it to political utility. Academy historians helped correct ideological distortions, interpret archives, support education, inform public debates, preserve institutional memory, contextualise anniversaries, professionalise oral history and connect Czech experience with European scholarship. Their task was not to provide society with a final authorised narrative of the past. It was to maintain the conditions under which the past could be investigated, discussed and revised responsibly. In this sense, historical expertise became one of the quiet foundations of Czech democratic culture: it taught that freedom requires not only access to memory, but also the discipline to interpret memory critically.

Sociology, Economics, Law, and Political Research

1. Social Transformation after 1989 as a Research Object

The social transformation after 1989 became one of the most important research objects for the social sciences of the Czech Academy of Sciences. It was not a narrow topic belonging only to sociology, economics or political science, because the transformation changed nearly every institutional and everyday dimension of Czech society. The fall of the communist regime altered property relations, class structures, labour markets, political representation, law, public administration, family strategies, educational pathways, social expectations and the moral vocabulary of citizenship. It also changed the status of expertise itself, because social scientists were no longer expected to explain society within the limits of Marxist-Leninist

doctrine or administrative planning. They could now investigate a rapidly changing society whose direction was uncertain and whose outcomes were deeply contested. The post-1989 transformation therefore became both an object of research and the condition under which research itself had to be reorganised (*Večerník & Matějů, 1999*; *Machonin, 1997*; *Elster, Offe, & Preuss, 1998*).

The Academy's social sciences entered the democratic period with a complicated inheritance. Under state socialism, sociology had been suppressed, revived, politically supervised and partially institutionalised in different phases, while economics had been closely tied to planning, reform debates and the official language of socialist development. Legal research had worked within a constitutional order in which the leading role of the Communist Party limited the autonomy of law, and political analysis could not openly study power competition in the liberal-democratic sense. After 1989, these fields had to redefine their professional identity. They had to reconnect with international theories, methods and standards, but they also had to study a local transformation whose speed and social consequences had few direct precedents. The Academy's role was therefore double: it had to modernise its own social-scientific disciplines while using them to understand the modernisation, disruption and re-stratification of Czech society.

The transformation was often described in the language of transition: from dictatorship to democracy, from plan to market, from state ownership to private property, from ideological monopoly to plural public life, and from Soviet bloc integration to European and global integration. Yet social research gradually showed that transition was not a simple movement from one fixed model to another. It involved conflicts over privatisation, inequality, welfare, justice, political trust, regional development, public administration, civil society and national identity. The end point was not immediately known, and the process was shaped by institutions inherited from socialism as well as by new market and democratic rules. Czech society did not begin again from zero in November 1989. It carried forward habits, skills, networks, inequalities, memories and expectations formed under the previous regime (*Stark & Bruszt, 1998*; *Szelényi & Szelényi, 1995*).

Sociology was especially well placed to study this process because transformation was lived not only in parliaments and ministries but in households, workplaces, schools, neighbourhoods and family biographies. The Institute of Sociology of the Academy of Sciences became one of the principal centres for monitoring changing social structure, values, political attitudes and public opinion. Large surveys conducted after 1989 investigated demographic and family status, education, cultural capital, economic position, income, consumption, mobility, political preferences, value orientations and subjective perceptions of social hierarchy. These studies helped transform social change from journalistic impression into empirical knowledge. They also made it possible to compare the late socialist structure with the emerging post-socialist order (*Večerník, 2002*; *Machonin, Tuček*, & *Gatnar, 1995*).

The project on the transformation of social structure in Czechoslovakia was particularly important because it addressed one of the central questions of the early 1990s: what kind of society was emerging from state socialism? Late socialist Czechoslovakia had often been described as relatively egalitarian, although this egalitarianism concealed differences in power, access, networks, education and informal advantage. The shift to market capitalism made inequalities more visible and more measurable. Income differences widened, new occupational hierarchies emerged, entrepreneurship became a route to mobility, and property

ownership acquired new significance. Sociologists had to ask whether these inequalities represented normal differentiation in a market society, the reproduction of old advantages in new forms, or the emergence of new class divisions. The answer was not ideological but empirical, requiring survey data, longitudinal comparison and theoretical analysis (*Večerník, 1996*; *Matějů & Kreidl, 2001*).

Class became a renewed object of inquiry after 1989, but it could no longer be treated through the rigid categories of official Marxism. Under socialism, class language had been ideologically saturated, often used to legitimise party power rather than analyse social reality. After the transition, sociologists had to rebuild class analysis in relation to education, occupation, income, ownership, cultural capital, labour-market position and subjective identification. This required dialogue with Western stratification theory as well as attention to post-socialist specificity. The new class structure did not simply copy Western capitalism, because it emerged from socialist employment patterns, state assets, restitution, voucher privatisation, professional networks and the rapid revaluation of skills. Research on class therefore became one of the most important ways of understanding the social consequences of the economic transformation.

The labour market was another central field of research. State socialism had promised full employment, although this promise was embedded in low productivity, hidden unemployment, rigid allocation and limited occupational choice. After 1989, unemployment became a visible social fact, and labour-market participation was reshaped by privatisation, restructuring, foreign investment, regional decline, new professions and changing gender roles. Economists and sociologists studied employment insecurity, wage differentiation, human capital, regional labour markets and the social effects of industrial restructuring. The transformation of work affected not only income but identity. Many citizens experienced the new market order through the loss of stable employment, the need for retraining, the rise of entrepreneurship or the discovery that formerly secure skills no longer guaranteed status.

Family and household research revealed another dimension of transformation. Economic reform changed household strategies, consumption, housing, intergenerational support and gender relations. Families had to adapt to price liberalisation, changing welfare provisions, new labour-market opportunities and increased uncertainty. The transition also altered life-course expectations, including marriage, fertility, parenthood, education and housing acquisition. Sociologists could therefore study transformation not only as institutional reform but as a reorganisation of everyday security. The household became a site where macroeconomic change was translated into decisions about work, children, migration, consumption and care. This was one of the reasons why longitudinal and survey-based research became so important in the early post-socialist decades.

Public opinion research became another crucial instrument of social diagnosis. The Czech public had entered democracy with high expectations, but attitudes towards reform, parties, markets, inequality, corruption, Europe and social justice changed over time. The Public Opinion Research Centre within the Institute of Sociology offered a systematic way of monitoring these changes. Public opinion data were especially important because democratic legitimacy depends not only on formal institutions but also on trust, participation and perceived fairness. Surveys could reveal whether citizens accepted market reforms, how they evaluated political institutions, how they viewed social inequality, and whether they trusted the

direction of post-1989 development. In this sense, public opinion research became part of the empirical infrastructure of democracy (*Linek, 2010*; *Večerník, 2002*).

The study of values was closely connected with public opinion. Post-socialist transformation was not only a change in institutions; it was a change in moral expectations. Citizens had to reinterpret responsibility, success, equality, freedom, solidarity, entrepreneurship, welfare and civic participation. Sociologists investigated whether Czech society became more individualistic, more meritocratic, more tolerant of inequality, more distrustful of politics or more open to European identity. Such questions could not be answered through ideological assertion. They required repeated surveys and comparison with other societies. International programmes such as the European Values Study, International Social Survey Programme and European Social Survey helped place Czech developments into a wider comparative framework.

Economics within the Academy also underwent a profound transformation. Before 1989, economic research had been constrained by the institutional logic of the planned economy, although reform debates and technical analysis had existed within limits. After the Velvet Revolution, the central research questions changed rapidly: privatisation, price liberalisation, macroeconomic stabilisation, enterprise restructuring, banking reform, labour markets, public finance, foreign investment and the formation of market institutions became urgent topics. The Economics Institute of the Academy and its cooperation with CERGE created a more internationally oriented research environment. Economic transformation was no longer analysed mainly as a political programme; it became a field of empirical and theoretical research connected with global economics (*Myant, 2003*; *Hanousek & Kočenda, 2011*).

The creation and development of CERGE-EI was especially important because it connected Czech economics with international graduate training, peer-reviewed research and global academic standards. The post-socialist transformation needed economists who could work with modern microeconomics, macroeconomics, econometrics, public finance, labour economics and institutional analysis. It also needed a new generation of researchers able to publish internationally and participate in policy debates without being confined to the intellectual habits of the planned economy. The Academy's economic research thus belonged to the broader rebuilding of Czech expertise after 1989. It helped replace ideological economics with analytical economics, though always within a social context marked by political choice and public consequence (*CERGE-EI, n.d.*; *Economics Institute of the CAS, 2024*).

Privatisation became one of the most controversial research objects of the transformation. It was presented politically as a necessary route from state ownership to market efficiency, but its social and institutional effects were uneven. Voucher privatisation, restitution, foreign investment, enterprise restructuring and the emergence of new owners changed the distribution of wealth and power. Economists examined efficiency, corporate governance, ownership concentration, banking links and the performance of firms. Sociologists and political scientists asked how privatisation affected legitimacy, inequality, elite formation and public trust. The transformation of property therefore linked economics with social stratification and political culture. It showed that markets are not simply mechanisms but institutional orders with social consequences (*Kočenda & Valachy, 2001*; *Myant, 2003*).

Legal research faced its own transformation. The rule of law after 1989 could not be established merely by replacing old statutes with new ones. The legal order had to absorb

constitutional change, human rights, property restitution, commercial law, administrative reform, judicial independence, European law and the legacy of socialist legality. The Institute of State and Law of the Academy had to analyse law not as an ideological instrument of the socialist state, but as an autonomous normative order within a democratic constitutional framework. This required renewed attention to legal theory, constitutionalism, private law, public law, international law and later European Union law. Legal research thus became central to understanding how political transformation becomes institutionalised (*Kühn, 2011*; *Blahož, Balaš, & Klíma, 2007*).

The legal dimension of transformation was visible in restitution and rehabilitation. The new democracy had to address confiscated property, political persecution, unjust convictions and the moral injuries of the communist regime. These processes required law to mediate between history and justice. Legal scholars could examine the limits of retroactivity, the meaning of legality under dictatorship, the status of former state acts, and the relationship between moral wrong and legal remedy. Such questions showed that post-1989 transformation was not only forward-looking. It also involved a legal reckoning with the past. Law became one of the principal languages through which society attempted to repair, or at least acknowledge, historical injustice.

Constitutional transformation added another layer. The Czech Republic had to define its institutions after the dissolution of Czechoslovakia, while also anchoring democracy, separation of powers, fundamental rights and judicial review. The creation of the Constitutional Court and the development of constitutional jurisprudence gave legal research new significance. Scholars studied how constitutional principles operated in practice, how courts interpreted rights, and how Czech constitutionalism related to European legal standards. The rule of law became a research problem as well as a political aspiration. It required attention to institutions, legal culture, judicial reasoning and public trust in law (*Kühn, 2011*).

Political research was not concentrated in a single Academy institute in the same way as sociology or economics, but it developed across sociology, contemporary history, law and related fields. The study of political parties, elections, public opinion, parliamentarianism, state institutions, democratic consolidation and political culture became an important part of the post-1989 social-scientific agenda. Political transformation had to be understood not only through constitutional rules but through behaviour, attitudes and organisational structures. Researchers examined the emergence of parties, the role of Civic Forum and its successors, electoral volatility, left-right self-placement, trust in institutions and the changing meaning of citizenship. The Czech case offered a particularly rich example of peaceful democratic transition combined with rapid economic reform and state dissolution (*Kitschelt et al., 1999*; *Linek, 2010*).

The study of civil society was another important post-1989 theme. Dissident discourse had emphasised civil society as a moral alternative to the party-state, but after 1989 civil society had to become an institutional and sociological reality. Researchers investigated associations, NGOs, civic participation, volunteering, protest, local initiatives and the relationship between citizens and the state. The results were often more ambivalent than the revolutionary rhetoric. Civic participation did not automatically flourish, distrust remained high in some areas, and political parties quickly occupied much of the democratic space. This made civil society an

important research object because it revealed the distance between the moral imagination of 1989 and the practical sociology of democracy.

Inequality gradually became one of the strongest themes linking sociology and economics. The early transition was often justified by the promise that temporary hardship would lead to prosperity and freedom. Over time, researchers could observe how social differences accumulated in income, education, housing, health, regional opportunity and labour-market security. Some inequalities reflected new meritocratic mechanisms; others reproduced inherited advantages or emerged from policy choices. The Czech Republic remained more egalitarian than some other post-socialist societies, but the transformation still produced meaningful social differentiation. Research on inequality therefore challenged both nostalgic images of socialist equality and celebratory images of market success (*Večerník, 2009*; *Matějů & Kreidl, 2001*).

Regional transformation also demanded attention. The benefits and costs of post-1989 change were not distributed evenly across the Czech lands. Prague and some dynamic urban regions benefited from services, foreign investment, administration, universities and international connections. Industrial and peripheral regions experienced restructuring, unemployment, demographic decline or lower educational opportunity. The study of regional inequality linked sociology, economics, geography and political behaviour. It also helped explain later differences in trust, voting patterns and attitudes towards European integration. Transformation was therefore not a single national experience but a spatially differentiated process.

Gender research revealed another set of transformations. State socialism had promoted women's employment and formal equality, but it had also maintained gendered divisions of care, politics and authority. After 1989, market reform, welfare change, unemployment, entrepreneurship and changing family policies affected women and men differently. Researchers studied gender roles, labour-market inequality, family policy, political representation and the relationship between paid and unpaid work. The transformation of gender relations showed that democracy and marketisation did not automatically produce equality. It also demonstrated that social research had to examine hidden forms of inequality that were not always visible in the language of class or income alone (*Hašková & Uhde, 2009*).

The study of education became equally important. Education was a key mechanism through which post-socialist mobility, inequality and cultural capital were reproduced. The expansion of higher education, changes in school governance, private educational options and new labour-market demands altered the relationship between family background and opportunity. Sociologists studied whether the transformation opened educational mobility or strengthened advantages for families with greater resources. This question was central because education was one of the main promises of democratic and market transformation: talent and effort were expected to matter more than political loyalty. Empirical research could test how far that promise was realised.

Migration and minority research gradually became more important as Czech society changed demographically and culturally. The Czech Republic moved from a society strongly shaped by emigration and relative ethnic homogeneity after the post-war expulsions towards a society with new immigration, foreign workers, refugees, Roma inclusion debates and European mobility. Public opinion research tracked attitudes towards foreigners, national groups and minority coexistence. Sociological and legal research examined integration, citizenship,

discrimination, labour migration and social policy. These topics showed that transformation after 1989 was not only the internal reorganisation of a post-communist society. It also involved the Czech Republic's entry into a more mobile and plural European environment.

The European Union became both an object and framework of research. Before accession in 2004, European integration shaped law, public administration, economic policy, political discourse and national expectations. After accession, it influenced governance, funding, labour mobility, regulatory standards, regional development and public identity. Economists studied convergence, trade, labour mobility and public finance; legal scholars examined European law and constitutional pluralism; sociologists studied European identity, trust and public attitudes; political researchers analysed parties, institutions and policy adaptation. European integration therefore transformed the research agenda itself. It forced Czech social sciences to study Czech society as part of a multi-level European order (*Vachudova, 2005*; *Fawn, 2000*).

Data infrastructure became essential for the study of transformation. Surveys, archives, longitudinal datasets, public opinion series and international comparative data allowed researchers to move beyond impressionistic accounts. The Czech Social Science Data Archive, established at the Institute of Sociology in 1998 and later connected with European data infrastructure, became an important tool for preserving and sharing social science data. This changed the culture of research by making datasets reusable, comparable and publicly documented. The transformation of society could be studied across time because data were archived rather than lost in individual projects. In this respect, social science infrastructure performed a role similar to archives and dictionaries in the humanities (*Czech Social Science Data Archive, n.d.*; *Večerník, 2002*).

The methodological transformation of the social sciences was itself part of the post-1989 story. Researchers had to adopt survey methodology, econometrics, comparative political analysis, legal theory, qualitative interviews, panel data, international datasets and interdisciplinary research designs. The rebuilding of disciplines required training, translation, international cooperation and competition for grants. Younger scholars increasingly entered international networks, while older scholars carried local knowledge of socialist institutions and early transformation. The strongest research emerged where these generations and methods interacted. Czech social science after 1989 was not merely imported Western theory applied to local material. It was a process of methodological renewal grounded in a unique historical case.

The Academy's social sciences also contributed to public debate. Researchers commented on inequality, pensions, education, public opinion, labour markets, corruption, legal reform, elections, European integration and social policy. This public role could be difficult because policy debate often demands immediate answers, while research requires qualification and evidence. Yet the Academy's public research status gave its institutes a special responsibility to provide independent expertise. Social scientists were expected neither to become politicians nor to withdraw into technical analysis. Their task was to help society diagnose itself with greater accuracy.

The concept of "social diagnosis" is especially useful for understanding this role. A doctor does not create the illness by naming it; a social scientist does not create inequality, distrust or institutional weakness by studying them. Diagnosis makes problems visible, measurable and discussable. After 1989, Czech society needed such diagnosis because transformation

produced winners and losers, hopes and disappointments, new freedoms and new vulnerabilities. The Academy's research helped identify these processes before they hardened into political myths. It showed that democracy requires empirical self-knowledge as well as constitutional design.

The transformation after 1989 also became a comparative case for international scholarship. Czech society was often discussed as one of the more successful post-communist transformations, with relatively stable democracy, lower inequality than some neighbours, and eventual integration into NATO and the European Union. Yet Czech research complicated this external image by examining corruption, distrust, regional disparities, social exclusion, party instability and dissatisfaction with politics. International comparison was therefore not only a way of presenting Czech success abroad. It was also a way of identifying hidden problems at home. The Academy's social sciences contributed to this comparative understanding by producing data and analysis that could speak beyond national boundaries.

The study of social transformation gradually changed over time. In the 1990s, the dominant questions concerned transition, privatisation, class formation, political institutions and immediate social costs. In the 2000s, attention shifted more strongly towards European integration, welfare reform, inequality, public policy and democratic consolidation. In the 2010s and 2020s, new questions emerged around populism, migration, ageing, digitalisation, climate policy, pandemic consequences and the social effects of global crises. Yet these later questions remained connected to the transformation period because they developed within the institutions, inequalities and political cultures created after 1989. The transformation did not end as a research object; it became the historical background of contemporary Czech society.

Thus, social transformation after 1989 became a central research object through which the Czech Academy of Sciences' social sciences redefined their purpose, methods and public relevance. Sociology studied class, mobility, values, public opinion, family, inequality and social structure; economics examined market institutions, privatisation, labour markets and policy consequences; legal research analysed constitutionalism, restitution, rule of law and Europeanisation; political research explored parties, institutions, trust, participation and democratic consolidation. Together these fields transformed the post-communist transition from a political slogan into a complex empirical and theoretical object. Their significance lay not only in explaining what changed after 1989, but in showing that freedom, markets and democracy are not abstract destinations. They are social processes that must be measured, interpreted, criticised and continually understood.

2. Public Policy, Governance, Inequality, and European Integration

The study of public policy, governance, inequality and European integration became one of the most important ways in which the social sciences of the Czech Academy of Sciences moved beyond the first post-1989 agenda of transition. In the early 1990s, the dominant question was how to move from state socialism to democracy and market capitalism. By the late 1990s and especially after the Czech Republic's accession to the European Union in 2004, the research agenda became more complex. Scholars no longer studied transformation only as a dramatic rupture with the communist past, but as a long process of institutional adaptation, social differentiation and policy learning. Public policy became a field in which social expectations,

legal norms, economic constraints and political decisions met. Governance became a way of analysing how power was exercised not only by the central state, but also by municipalities, regions, courts, agencies, expert bodies, European institutions and civil society. Inequality became a test of the social consequences of freedom and market reform. European integration became both a research object and a framework that reshaped Czech law, administration, politics and social science itself (*Večerník, 2009*; *Vachudova, 2005*; *Potůček, 2004*).

The post-1989 Czech state had to learn democratic policy-making while simultaneously carrying out economic reform, institutional rebuilding and international integration. This meant that public policy was not a settled administrative routine, but part of the transformation itself. Decisions on privatisation, pensions, housing, education, health care, taxation, regional development, labour regulation, social benefits and local government were made under conditions of uncertainty and political urgency. Social scientists could therefore study policy not only through formal programmes, but through implementation, unintended consequences, public legitimacy and institutional learning. The Academy's research helped reveal that policy is not merely a technical instrument applied to society from above. It is a social process in which expert knowledge, political conflict, administrative capacity and public trust interact.

Governance became an especially useful concept because the Czech Republic after 1989 was not governed by a single hierarchical centre in the way imagined by the socialist planned state. Power became dispersed across elected institutions, ministries, courts, municipalities, regional governments, independent agencies, political parties, employers, trade unions, civic organisations, European bodies and international markets. The study of governance allowed researchers to ask how decisions were coordinated, how conflicts were mediated, how responsibility was distributed and how public authority was made legitimate. This was particularly important in a country with thousands of municipalities, strong local identities and a post-communist distrust of centralised power. The social sciences therefore moved from studying "the state" in the abstract to studying the concrete arrangements through which public decisions were produced and implemented (*Illner, 2003*; *Kostelecký, 2005*).

Local and regional governance became one of the most significant fields in this respect. After 1989, the Czech Republic restored municipal self-government and later created regional self-government, thereby changing the territorial structure of public authority. These reforms were not merely administrative. They affected local democracy, service provision, regional development, political representation and the ability of citizens to influence public decisions. Researchers at the Institute of Sociology studied local government cooperation, municipal fragmentation, endogenous development potential, regional disparities and the social capital of communities. Such work showed that democratic governance is not secured only by national elections. It also depends on the capacity of local institutions to solve problems, cooperate and represent citizens effectively (*Illner, 2003*; *Bernard, 2012*).

Municipal fragmentation created a distinctive Czech problem of governance. Many municipalities are small, and smallness can preserve local identity and proximity between citizens and representatives, but it can also weaken administrative capacity, professional expertise and development planning. Inter-municipal cooperation therefore became an important topic for social research. Scholars examined whether small municipalities could provide services, attract investment, manage infrastructure and participate in regional development without losing democratic responsiveness. The question was not whether local self-government was good or bad, but how it could function under conditions of unequal

resources. This made governance a matter of institutional design and social geography at the same time.

The spatial dimension of inequality became increasingly important as the transformation matured. In the early 1990s, inequality was often discussed in terms of income, class and labour-market position. Later, researchers paid more attention to place: metropolitan growth, suburbanisation, peripheral decline, housing markets, regional labour opportunities, access to education and the geography of political attitudes. The department of local and regional studies at the Institute of Sociology placed social and spatial inequalities among its key research concerns. This was crucial because social hierarchies are not distributed evenly across territory. A person's opportunities depend not only on education and occupation, but also on whether they live in Prague, a prosperous regional centre, a declining industrial area, a small municipality or an internally marginalised locality (*Ouředníček, Temelová, & Pospíšilová, 2011*; *Bernard, 2012*).

Metropolitan governance illustrates the connection between policy, inequality and spatial change. Prague and other metropolitan areas concentrate employment, higher education, services, cultural capital, research institutions and political influence. At the same time, metropolitan expansion produces housing pressure, commuting, suburbanisation, segregation and unequal access to public goods. Research on governance in metropolitan areas therefore asks how institutional structures and specific policies affect socio-spatial inequality. This is not a purely urban-planning question. It is a question of social justice, because metropolitan development can distribute opportunities unevenly between centre, suburbs, peripheries and different social groups. The Czech case also invites comparison with Western Europe, North America and other Central European societies, where metropolitan governance has long been tied to debates on inequality and cohesion (*Sýkora & Bouzarovski, 2012*; *Ouředníček et al., 2011*).

Housing policy became one of the most visible areas where social transformation and inequality met. The post-1989 shift from state-regulated housing allocation to a more market-based housing system involved restitution, privatisation of municipal housing, rent deregulation, mortgage expansion, suburbanisation and growing differences between owners, tenants and new entrants to the housing market. Sociological research on housing affordability, Prague's housing market and socio-economic access to housing showed that property reform could produce new inequalities even in a society that had inherited relatively broad housing security from socialism. Housing is not only a commodity. It is a condition of family formation, intergenerational mobility, spatial belonging and social security. Research on housing therefore linked public policy with everyday life in a particularly direct way (*Lux, 2009*; *Lux & Sunega, 2014*).

Inequality after 1989 was never only economic. It involved education, gender, region, ethnicity, health, housing, family background, labour-market position and cultural capital. The Czech Republic remained comparatively less unequal than many post-socialist countries, but the social meaning of inequality changed because the moral language of society changed. Under socialism, official discourse emphasised equality while concealing privileges connected with party position, networks and access. After 1989, inequality became more visible and partly legitimised through the language of merit, entrepreneurship and individual responsibility. Social scientists had to examine where meritocratic differentiation ended and structural

disadvantage began. This question became one of the central problems of Czech sociology (*Matějů & Kreidl, 2001*; *Večerník, 2009*).

Education was one of the crucial mechanisms through which inequality was reproduced or challenged. Democratic transformation promised that social advancement would depend less on political loyalty and more on talent, effort and education. Yet educational opportunity remained strongly influenced by family background, parental education, cultural resources and regional conditions. Sociological research therefore examined access to secondary and higher education, the expansion of tertiary education, social selection, educational aspirations and the relationship between credentials and labour-market outcomes. These questions were central to public policy because education is both a private route to mobility and a public investment in human capital. If educational inequalities harden, democratic society risks reproducing privilege under the language of merit.

Gender inequality formed another important policy field. The transition to democracy and market economy did not automatically create gender justice. Women's employment, childcare, parental leave, wage gaps, political representation, work-life balance, flexible work and the distribution of unpaid care all became subjects of research. Gender studies within the Institute of Sociology contributed to the analysis of equal opportunities policies, especially in relation to European standards and EU accession. This research showed that European integration could function as a normative and policy pressure for gender equality, but also that formal compliance did not guarantee deep social change. Gender equality therefore became a field where law, policy, workplace culture and everyday family practices had to be studied together (*Hašková & Uhde, 2009*; *Čermáková et al., 2000*).

Work-life balance became one of the clearest examples of a policy problem requiring sociological expertise. Flexible work, parental responsibilities, employer practices, social policy and gender relations all interact in shaping how individuals and families organise their lives. Research on work-life balance exposed the gap between formal rights and real possibilities. It also revealed how public policy can support or constrain gender equality through childcare provision, parental leave design, labour regulation and employer incentives. Such research moved social science beyond description towards policy relevance. It did not dictate one political solution, but it clarified the consequences of different institutional arrangements.

The Roma question and the broader issue of social exclusion also became central to public policy and inequality research. Roma communities faced long-term disadvantages in education, housing, labour markets, health, public perception and relations with local authorities. These inequalities could not be explained only by individual behaviour; they were connected with discrimination, segregation, regional disadvantage, institutional practices and historical marginalisation. Social research helped make these structural dimensions visible. It also challenged the majority society's tendency to interpret social exclusion through moral stereotypes. In this field, expert knowledge had a strong democratic function because it translated a politically sensitive issue into a matter of rights, institutions and social policy.

Public opinion research was indispensable for understanding governance and policy legitimacy. The Public Opinion Research Centre provided long-term data on citizens' trust in institutions, political attitudes, satisfaction, value orientations and perceptions of social problems. Such research matters because policy failure is not only a technical matter; it is also a failure of trust, communication and legitimacy. A reform may be economically rational but

politically fragile if citizens perceive it as unfair, corrupt or incomprehensible. Conversely, public support may exist for policies that are difficult to implement institutionally. Public opinion research therefore became part of the democratic feedback system, helping scholars and policymakers understand how society interprets governance (*Linek, 2010*; *Červenka, 2020*).

Trust became one of the key themes of post-1989 political and sociological research. The communist regime had damaged trust in official institutions, but the new democracy did not automatically create high confidence in parties, parliament, government, courts or public administration. Corruption scandals, party instability, economic uncertainty and unmet expectations all affected political trust. At the same time, interpersonal trust, social capital and civic participation influenced the quality of local governance and democratic cooperation. Research on trust and European integration showed that confidence in domestic and European institutions cannot be understood separately. Citizens evaluate the European Union partly through national political experience and evaluate domestic institutions partly through comparison with European standards (*Mishler & Rose, 2001*; *Linek, 2010*).

European integration reshaped the Czech research agenda in several ways. Before accession, it was a process of conditionality, legal approximation, administrative reform and political aspiration. After accession, it became a permanent framework of governance. EU membership affected public law, economic policy, regional development, social policy, gender equality, migration, environmental regulation, research funding and the circulation of expertise. For social scientists, this meant that Czech society could no longer be studied only within national borders. Laws, policies and public expectations were increasingly embedded in multi-level governance. European integration therefore transformed both the object of research and the conceptual tools required to study it (*Vachudova, 2005*; *Schimmelfennig & Sedelmeier, 2005*).

Legal research played a crucial role in analysing Europeanisation. The Institute of State and Law of the Academy had to engage with the relationship between Czech constitutional order, European Union law, international law and domestic legal culture. EU accession required not only the adoption of legal norms but the transformation of administrative practices, judicial reasoning and regulatory frameworks. Legal scholars examined how European law interacted with Czech constitutional principles, how courts interpreted supranational obligations, and how the rule of law operated in a multi-level legal order. European integration thus made governance legally plural. The Czech state remained sovereign, but its legal and policy environment became deeply interconnected with European institutions (*Kühn, 2011*; *Bobek, 2012*).

European integration also reshaped economic research. EU membership affected trade, competition, public finance, labour mobility, structural funds, regional development, regulation and convergence. Economists could study how Czech firms adapted to the single market, how foreign direct investment shaped productivity, how EU funds affected regional development, and how fiscal and monetary policy operated in relation to European constraints. The Economics Institute and CERGE-EI contributed to internationally oriented economic research capable of linking Czech issues with broader empirical and theoretical debates. In this context, public policy became increasingly evidence-based and comparative. Czech economic problems could be studied alongside those of other EU members, especially in Central and Eastern Europe (*Hanousek & Kočenda, 2011*; *Fidrmuc, 2003*).

The IDEA think tank at CERGE-EI represented a particularly clear example of the movement from academic economics towards policy-oriented expertise. Its analyses addressed education, labour markets, public finance, pensions, taxation, public administration, family policy, the pandemic, migration and other socially relevant questions. This form of expert work did not replace academic research, but translated it into formats more usable for policymakers, journalists and citizens. It showed that the Academy's contribution to public policy could include rapid analytical responses as well as long-term scholarly projects. The challenge was to maintain academic rigour while entering a public sphere that often demands concise conclusions and immediate relevance.

Regional development and cohesion policy became one of the strongest links between European integration and domestic inequality. EU structural and cohesion funds were intended to reduce disparities, support infrastructure, strengthen competitiveness and promote regional development. Yet their effects depended on administrative capacity, local governance, project design and political priorities. Social scientists could therefore examine not only how much money flowed into regions, but how it was used, who benefited, and whether it reduced or reproduced inequalities. European policy became meaningful only through domestic institutions. This made regional governance a core field of research on Europeanisation.

The study of public administration was also essential. Post-communist governance required professional, transparent and accountable administration, but the Czech state inherited bureaucratic habits from socialism and developed new problems in the transition period. Administrative reform, decentralisation, civil service law, public procurement, regulatory agencies and policy coordination all became research concerns. Good governance could not be reduced to electoral democracy. It required competent institutions capable of implementing policy fairly and predictably. Social-scientific and legal expertise helped identify where administrative capacity was weak and where institutional reform was necessary.

Corruption became a recurring theme in Czech public debate and research. It was often interpreted as a moral failure of individuals, but social science showed that corruption also reflects institutional incentives, weak oversight, party financing, public procurement rules, opaque ownership structures and low trust. Research on governance therefore had to address corruption as a systemic problem rather than a collection of scandals. This was important for European integration as well, because EU norms and funds increased attention to transparency, accountability and audit. The Academy's social sciences could contribute by connecting public perceptions of corruption with institutional analysis and policy design.

The politics of inequality became increasingly visible in electoral behaviour. Social and regional disparities influenced voting patterns, party support and attitudes towards democracy, Europe and migration. Researchers studied electoral geography, political participation, Senate and parliamentary elections, party competition and the persistence or change of voting patterns across Czech territory. Such research revealed that policy outcomes shape political behaviour over time. Regions that feel neglected or groups that experience insecurity may express dissatisfaction through distrust, abstention or support for protest parties. The study of inequality therefore became inseparable from the study of democratic governance (*Linek, 2010*; *Kostelecký, 2015*).

The relationship between expertise and policy was not without tension. Policymakers may seek clear recommendations, while researchers often identify trade-offs, uncertainties and

unintended consequences. Social scientists may be invited to legitimise policies already chosen, rather than to shape policy through evidence. Expert knowledge can also become politically contested when it touches on pensions, taxes, gender equality, housing, migration or regional redistribution. The Academy's value lies in its relative autonomy. It can provide policy-relevant knowledge without becoming a department of government. This autonomy is essential because evidence-informed policy requires researchers who can criticise as well as advise.

The COVID-19 pandemic later demonstrated the importance of social-scientific policy expertise beyond the traditional transformation agenda. Questions of public trust, risk communication, family stress, education disruption, labour-market vulnerability, state capacity and public compliance became central to crisis governance. Economists, sociologists and legal scholars all had roles in analysing the social effects of emergency measures and the distribution of burdens. The pandemic showed that governance is not only a matter of ordinary administration but also of social resilience. It also revealed that inequality can intensify rapidly when crisis affects households, workers, children and regions unevenly.

Climate and energy policy introduced another layer of Europeanised governance and inequality. The Czech Republic's industrial structure, coal regions, energy dependence, household costs and EU climate commitments created difficult policy choices. A socially blind ecological transition could deepen regional and class inequalities; a delayed transition could create economic and environmental risks. Although climate policy is often associated with natural sciences and technology, its success depends on social acceptance, governance, compensation, labour-market adaptation and public trust. The Academy's social sciences are therefore increasingly necessary for understanding the societal conditions of environmental transformation.

Migration and integration policy also linked Czech governance with European and global processes. The Czech Republic had to respond to labour migration, EU mobility, refugee crises and changing public attitudes towards foreigners. These issues tested administrative capacity, public communication, education systems, labour markets and local integration. Sociological research could distinguish between perception and reality, between prejudice and measurable social processes, and between short-term political mobilisation and long-term demographic change. European integration made migration policy a multi-level issue, shaped by domestic politics, EU frameworks and international crises.

Public policy research also benefited from data infrastructures. The Czech Social Science Data Archive, public opinion series, European Social Survey, International Social Survey Programme and other comparative datasets provided evidence for studying values, trust, inequality, identity and policy preferences. Data infrastructure is not only a technical matter. It creates the possibility of cumulative research and public accountability. When data are archived, documented and accessible, claims about society can be tested and compared. This is one of the ways in which the Academy supports evidence-informed governance.

The social sciences of the Academy thus stood between long-term research and immediate public relevance. Sociology diagnosed inequalities, public attitudes and social processes; economics analysed incentives, markets and policy costs; legal research examined rules, rights and institutional frameworks; political research interpreted governance, representation and Europeanisation. Together these fields formed a knowledge infrastructure for democratic society. They did not eliminate political conflict, and they could not decide normative

questions on behalf of citizens. But they made conflict more informed by showing what is at stake, who is affected and what consequences different policies may have.

The study of public policy, governance, inequality and European integration also changed the meaning of expertise itself. Under socialism, expertise had often been subordinated to plan targets and ideological priorities. After 1989, expert knowledge became more plural, competitive and internationally connected, but also more exposed to public scepticism. The Academy had to earn trust through methodological quality, transparency and public communication. Its social-scientific work showed that democratic expertise should not command society from above. It should provide citizens and policymakers with reliable knowledge for making difficult choices.

Thus, the research agenda of public policy, governance, inequality and European integration became a mature stage in the Academy's post-1989 social sciences. It moved beyond the initial narrative of transition and examined the concrete functioning of democratic capitalism, local and regional governance, social stratification, legal Europeanisation, public trust and policy capacity. The Academy's contribution lay in connecting empirical data with institutional analysis and public relevance. It showed that democracy is not only a constitutional form, markets are not only economic mechanisms, and European integration is not only a diplomatic orientation. All three are lived through policies, inequalities, institutions and everyday expectations. By studying these processes, the Academy helped Czech society understand not only where it had come from after 1989, but how it was being governed, divided, integrated and transformed in the present.

3. The Academy's Contribution to Social Diagnosis and Expert Knowledge

The contribution of the Czech Academy of Sciences to social diagnosis and expert knowledge after 1989 should be understood as one of the central functions of its social sciences. Social diagnosis means more than the description of social facts. It is the disciplined identification of processes, risks, inequalities, expectations and institutional weaknesses that may not yet be fully visible in political debate or everyday experience. In this sense, sociology, economics, law, psychology and political research helped Czech society look at itself with greater empirical precision. They translated scattered impressions into data, public anxiety into research questions, and political slogans into analysable institutional problems. The Academy's role was not to govern society directly, nor to replace democratic decision-making with expert rule. Its task was to provide the kind of independent knowledge without which democratic choices become vulnerable to myth, improvisation and ideological simplification (*Academy of Sciences of the Czech Republic, n.d.*; *Potůček, 2004*; *Večerník, 2009*).

This role became especially important because post-1989 Czech society experienced a double movement. It became freer, more plural and more open to international comparison, but also more exposed to uncertainty, inequality, political distrust and economic risk. Citizens had to interpret new phenomena such as unemployment, private ownership, regional differentiation, party competition, European integration, migration, public opinion polling, market-based housing and changing welfare institutions. These were not merely political issues; they were changes in the texture of everyday life. The Academy's social sciences helped convert this experience into knowledge that could be compared, measured and debated. Social diagnosis therefore became one of the instruments through which the post-socialist society could

understand the consequences of its transformation (*Večerník & Matějů, 1999*; *Machonin, 1997*).

The Institute of Sociology was especially important in this process because it developed empirical tools for observing contemporary Czech society. Established in its present form in 1990, it conducted ongoing and one-time empirical surveys, comparative research, public opinion surveys and case studies, using both quantitative and qualitative methods. Its research covered social stratification, values, family, gender, public opinion, local and regional development, education, migration, religion, trust, political attitudes and social inequality. This made the institute one of the Academy's principal centres of social diagnosis. It did not merely analyse society from a theoretical distance. It built the empirical infrastructure that allowed Czech social change to be observed across time (*Institute of Sociology of the CAS, n.d.*; *Večerník, 2002*).

The Public Opinion Research Centre played a special role because it monitored the changing attitudes of Czech citizens on political, economic and social questions. Public opinion surveys are not a substitute for democracy, but they are an important democratic instrument. They reveal how citizens evaluate institutions, reforms, parties, living conditions, international developments and social problems. They also show that public opinion is not a fixed national temperament but a changing field shaped by events, expectations and trust. In a post-authoritarian society, such knowledge has particular value because official declarations no longer define what society is supposed to think. The Academy's public opinion research helped make citizens' attitudes visible without reducing them to propaganda or anecdote (*Public Opinion Research Centre, n.d.*; *Linek, 2010*).

Public opinion research also gave society a temporal mirror. A single survey can indicate a mood, but time series can reveal patterns, turning points and long-term shifts. Trust in constitutional institutions, satisfaction with the political situation, attitudes towards Europe, perceptions of inequality, evaluations of economic conditions and views on public problems acquire meaning when they are followed over years. This makes it possible to distinguish between temporary reactions and deeper tendencies. The social role of such research is therefore not merely informational. It helps citizens, journalists, policymakers and scholars see whether Czech democracy is accumulating trust, losing confidence, polarising or stabilising. Social diagnosis depends precisely on this capacity to observe society in motion.

The Czech Social Science Data Archive gave this diagnostic function a deeper infrastructural form. By acquiring, processing, documenting, preserving and making available digital data from social science research, it helped ensure that social knowledge would not disappear after individual projects ended. Data archiving is not a technical accessory to research; it is a condition of cumulative social science. It allows future researchers to reanalyse survey data, compare periods, test new hypotheses and teach empirical methods. In this respect, the data archive performs for sociology and political research a function comparable to that of archival collections, dictionaries and bibliographies in the humanities. It preserves the empirical memory of society (*Czech Social Science Data Archive, n.d.*).

The international dimension of data infrastructure was also important. Czech social science became more credible and useful when its data could be compared with European and global research. Participation in international survey programmes and European data infrastructures helped place Czech developments within broader patterns of post-socialist transformation, democratic consolidation, value change and social inequality. This comparison protected

Czech research from provincialism. It also protected public debate from the illusion that Czech problems were either entirely unique or simply identical to those of other countries. Good social diagnosis requires comparison because only comparison reveals whether a phenomenon is local, regional, European or global.

Economics contributed another form of expert knowledge. After 1989, economic expertise was urgently needed because the transformation from plan to market involved price liberalisation, privatisation, banking reform, public finance, labour markets, taxation, pensions, education, innovation and integration into European and global markets. The Economics Institute of the Czech Academy of Sciences, operating as a joint workplace with CERGE of Charles University, helped connect Czech economics with international research standards. Its role was not only to explain the transition retrospectively. It trained and sustained a community capable of analysing contemporary policy through modern economic theory, econometrics and empirical evaluation. This was a major change from the ideological and administrative economics of the planned system (*CERGE-EI, n.d.*; *Economics Institute of the CAS, 2024*).

The IDEA think tank at CERGE-EI illustrates how Academy-based economic expertise could enter public debate without becoming partisan political commentary. It focused on policy-relevant research, evaluation and recommendations grounded in data, facts, impartial interpretation and modern economic theory. Its analyses addressed education, pensions, taxation, labour markets, family policy, public administration, research funding, pandemic effects and other socially significant issues. This form of expertise is important because modern public policy often requires not only general principles but careful assessment of incentives, costs, distributional effects and unintended consequences. The Academy's contribution lay in providing evidence-based economic reasoning in a public environment where economic debates could easily become ideological (*Institute for Democracy and Economic Analysis, n.d.*).

Legal expertise added a different but equally necessary dimension. The Institute of State and Law served as a centre of non-university legal research, examining law, legal theory, legal informatics, constitutional questions, European law, public law, private law and international cooperation. After 1989, legal knowledge was indispensable because democratic transformation required more than political will. It required legal continuity, constitutional order, rights protection, administrative legality, judicial independence, property regulation and later integration into European Union law. Legal expertise helped translate political transformation into normative institutions. It also clarified the limits of political action by reminding society that democracy depends on rules as well as elections (*Institute of State and Law of the CAS, n.d.*; *Kühn, 2011*).

The social diagnostic function of legal research became especially visible in questions of transitional justice, restitution, lustration and constitutionalism. These were not merely technical legal issues. They concerned the relationship between past injustice and present legality. Legal scholars had to ask how far a democratic state could repair past wrongs, how it should treat acts committed under a non-democratic legal order, and how rights could be protected without undermining legal certainty. Such questions required both legal doctrine and historical consciousness. The Academy's legal research helped society understand that justice after dictatorship cannot be reduced to moral desire; it must be articulated through sustainable legal principles (*David, 2003*; *Kühn, 2011*).

Psychology expanded the Academy's expert contribution by examining individual and social functioning, personality, development, social behaviour, health, political attitudes and cross-cultural questions. The Institute of Psychology brought attention to dimensions that cannot be captured by economics or legal research alone: trust, motivation, identity, stress, values, life-course development, social perception and the psychological conditions of democratic life. This mattered because transformation was not only institutional; it was also psychological. Citizens had to adapt to uncertainty, choice, competition, public disagreement and changing norms. Social diagnosis is incomplete if it measures institutions and income but ignores the human capacities and vulnerabilities through which those institutions are experienced (*Institute of Psychology of the CAS, n.d.*; *Klicperová-Baker, 1999*).

The psychological study of democracy was particularly relevant in a society emerging from authoritarianism. Democracy is not sustained only by constitutions; it also requires tolerance, trust, responsibility, willingness to participate, acceptance of pluralism and resistance to manipulation. Political psychology could therefore help explain why citizens support or distrust institutions, how authoritarian attitudes persist, how collective identities are formed, and why social frustration may produce anti-democratic temptations. Such research joined psychology with sociology and political science. It showed that expert knowledge about democracy must include both institutional design and the psychological dispositions of citizens (*Klicperová-Baker, 1999*; *Linek, 2010*).

The Academy's contribution to expert knowledge was strengthened by its position as a public non-university research institution. This position gave its institutes a special balance: they were supported as part of the public research system, but they were not ministries, political parties or commercial consultancies. Their authority depended on scientific autonomy, peer review, long-term research and public credibility. This mattered because expert knowledge is valuable only when it is trusted as independent. If expertise becomes merely the language of government, it loses critical force; if it becomes purely private opinion, it loses institutional responsibility. The Academy's social sciences occupied a middle ground between public relevance and scholarly autonomy.

Strategy AV21 made this public orientation more explicit by framing Academy research around problems and challenges of contemporary society. Its emphasis on interdisciplinary research in the public interest gave social sciences an opportunity to cooperate with natural sciences, technical fields, medical research and humanities. Problems such as ageing, health, education, energy, artificial intelligence, public policy, social resilience and democratic trust cannot be solved by a single discipline. The social sciences contribute by asking how technologies are governed, how policies are received, how risks are distributed, and how citizens understand expert recommendations. In this sense, social diagnosis became part of a broader interdisciplinary architecture (*Academy of Sciences of the Czech Republic, n.d.*).

The COVID-19 pandemic revealed the importance of this architecture. Although virology, medicine and epidemiology were central, the crisis also involved public trust, legal restrictions, economic compensation, family stress, education disruption, misinformation, risk communication and compliance with public measures. Economists analysed the effects of restrictions and support schemes; sociologists examined public attitudes and inequalities; psychologists studied stress and behaviour; legal scholars considered emergency powers and rights; communication experts addressed the public interpretation of scientific knowledge. The

crisis showed that expert knowledge is not a luxury added to governance after decisions are made. It is part of the capacity to govern under uncertainty.

The same applies to other long-term challenges. Ageing requires demographic, economic, psychological, legal and policy expertise. Housing affordability requires sociology, economics, law and regional studies. Educational inequality requires survey data, policy evaluation, family sociology and labour-market analysis. Climate transition requires technological knowledge, but also social acceptance, regional compensation and governance. Digitalisation and artificial intelligence require computer science, ethics, law, labour economics and social research. The Academy's social sciences therefore contribute by identifying the human and institutional dimensions of problems that might otherwise be treated as purely technical.

Inequality remained one of the most important objects of social diagnosis. It is not enough to know that a society is growing economically; one must know who benefits, who is left behind, which regions decline, which households face insecurity, and how inequalities are reproduced through education, housing, gender, health and labour markets. Academy research helped show that Czech inequality is multidimensional. Income measures are necessary, but they do not capture the full picture of social disadvantage. Spatial inequality, educational selection, housing insecurity, family background and exclusion from networks may be just as important. Social diagnosis therefore prevents policy from mistaking aggregate success for general well-being (*Večerník, 2009*; *Lux & Sunega, 2014*).

Public trust became another central diagnostic indicator. Trust in parliament, government, courts, media, experts, science, the European Union and fellow citizens affects how society responds to reform, crisis and conflict. Low trust can weaken even technically sound policies, while misplaced trust can expose society to manipulation. The Academy's social sciences helped examine trust as an empirical phenomenon rather than a moral complaint. Public opinion surveys, political research and psychological studies all contributed to understanding why trust rises or falls. This was especially important in a post-communist context, where distrust of official authority had deep historical roots (*Mishler & Rose, 2001*; *Linek, 2010*).

Expert knowledge also had to face the problem of populism and anti-expert sentiment. Democratic societies may need expertise, but citizens may also suspect experts of elitism, detachment or political bias. This tension intensified when expert recommendations touched on painful issues such as taxation, pensions, vaccination, migration, climate policy, housing or budget constraints. The Academy could not solve this tension by simply asserting authority. It had to communicate methods, data and uncertainty more clearly. The social role of expertise depends not only on being correct, but on being intelligible and accountable to the public.

This is why public communication became part of the Academy's expert mission. Press releases, policy briefs, public lectures, media commentary, databases, open data and educational resources all helped bring research into social circulation. Yet communication had to avoid oversimplification. The public value of the Academy lies in its ability to explain complexity without hiding behind jargon. In the social sciences, this means showing why a policy may help one group while burdening another, why public opinion may be contradictory, why legal solutions have limits, and why economic efficiency does not automatically equal social justice. Expert knowledge becomes socially useful when it clarifies choices rather than pretending that choices do not exist.

The Academy's contribution to expert knowledge was also generational. It trained young researchers through doctoral cooperation, international projects, methodological workshops

and research infrastructures. This mattered because expertise is not only a set of reports; it is a professional community capable of renewing itself. Post-1989 Czech social sciences had to build a new generation able to work with international literature, advanced methods and Czech empirical material. The sustainability of social diagnosis depends on such generational renewal. Without it, expertise becomes dependent on a few senior voices and loses methodological vitality.

Internationalisation strengthened expert knowledge by exposing Czech research to comparison and peer evaluation. Participation in European data infrastructures, international survey programmes, economic research networks, legal scholarship and comparative policy studies helped raise standards and expand relevance. It also allowed Czech society to be studied as part of broader European processes rather than as an isolated national case. At the same time, Academy researchers could contribute Czech evidence to international debates on post-socialist transformation, inequality, democracy, trust and Europeanisation. Expert knowledge therefore flowed in both directions: Czech research learned from the world and offered the Czech case to the world.

The Academy's social sciences also helped protect society from the illusion of purely technical governance. Many public problems appear technical because they involve budgets, legal provisions, indicators or administrative mechanisms. Yet behind these technical forms are social choices: who pays, who benefits, whose risks matter, whose voice is heard, and which future is preferred. Sociology, economics, law and psychology make these choices visible. They do not remove political responsibility, but they prevent responsibility from being hidden behind technical language. This is one of the most important democratic functions of expert knowledge.

At the same time, expert knowledge must recognise its limits. Social systems are complex, and evidence rarely eliminates uncertainty completely. Policies may have unintended consequences; public attitudes may change; data may be incomplete; international models may not fit local contexts. The Academy's strongest contribution lies not in pretending to possess final answers, but in cultivating disciplined uncertainty. Good expertise states what is known, what is probable, what is contested and what remains unknown. This intellectual modesty is not weakness. It is a condition of trustworthy advice.

The Academy's contribution to social diagnosis also included memory of transformation. By preserving data, studies, reports and analyses from the 1990s onwards, it created a record of how Czech society changed across decades. This record allows later researchers to ask whether early promises were fulfilled, which reforms had long-term effects, and how citizens' expectations evolved. The social sciences therefore provide historical depth for the present. They show that contemporary problems are rarely sudden; they often grow from earlier institutional choices, demographic trends and social inequalities.

The interaction between social sciences and humanities is important here. Historians study the past, while sociologists and economists often study the present, but the boundary is porous. Post-1989 transformation is now historical as well as sociological. Public opinion time series are archives of democratic experience. Economic datasets are sources for the history of capitalism. Legal debates reveal the institutionalisation of values. Psychological research records changing forms of subjectivity. The Academy's broader humanities and social-science environment allows these forms of knowledge to speak to one another.

The contribution of expert knowledge also extends to national self-understanding. Czech society often describes itself through narratives of scepticism, pragmatism, egalitarianism, secularism, small-state vulnerability, democratic tradition or distrust of authority. Social science can test, complicate or historicise these self-images. It can show where they correspond to data and where they function as myths. This is not an attack on national identity. It is a form of intellectual maturity. A society capable of examining its self-descriptions is better prepared to respond to change.

The Academy's social-scientific expertise therefore became part of democratic culture in a broad sense. Democracy requires elections, parties and rights, but it also requires knowledge of social conditions. Citizens cannot deliberate well if they do not understand inequality, trust, institutional performance, demographic change, economic trade-offs or legal constraints. Policymakers cannot govern well if they rely only on intuition, ideology or short electoral cycles. The Academy's role was to sustain a public reservoir of evidence and interpretation. This reservoir did not determine policy, but it improved the conditions under which policy could be made.

Thus, the Academy's contribution to social diagnosis and expert knowledge after 1989 lay in creating a durable system of independent, empirical and interdisciplinary understanding of Czech society. The Institute of Sociology, the Public Opinion Research Centre, the Czech Social Science Data Archive, the Economics Institute and IDEA, the Institute of State and Law, the Institute of Psychology and related research teams all helped identify social risks, institutional weaknesses, inequalities, public attitudes, legal dilemmas and policy consequences. Their work showed that a democratic society cannot rely only on memory, political will or economic growth. It needs instruments for observing itself, questioning itself and correcting itself. In this sense, the Academy's social sciences became one of the quiet but essential foundations of Czech democratic governance: they turned social experience into evidence, evidence into interpretation, and interpretation into a resource for public reason.

Strategy AV21, Innovation, and Science in the Public Interest

Chapter Thirteen

Strategy AV21: From Classical Academy to Public-Interest Research Institution

The Origins and Rationale of Strategy AV21

1. Why the Academy Needed a New Strategic Format

By the beginning of the second decade of the 21st century, the Czech Academy of Sciences had already passed through the most dramatic stages of its post-socialist transformation. It had survived the institutional rupture of the early 1990s, the dissolution of the Czechoslovak Academy of Sciences, the creation of a new republican academy, the redefinition of its legal status, and the long adjustment to competitive funding, international evaluation, and European research frameworks. Yet survival and stabilisation were no longer enough. The Academy faced a different kind of question: not whether it should exist, but how it should explain its necessity in a society where science was increasingly expected to justify itself in public, economic, environmental, technological, and cultural terms. The old academic language of excellence, disciplinary continuity, and institutional prestige remained important, but it no longer fully answered the demands placed upon a national research institution in a democratic, market-oriented, and globally connected state. The Academy therefore needed a new strategic format because its legitimacy had to be expressed not only through publications, institutes, and scholarly authority, but also through visible responses to the problems of contemporary society. Strategy AV21 emerged from this need to translate the Academy's traditional strengths into a modern public mission (*Czech Academy of Sciences, 2015*; *Czech Academy of Sciences, 2017*).

The deeper logic of this turn becomes clearer when it is placed against the earlier history of the Academy as an institution moving between autonomy and public responsibility. The learned societies of the Czech lands had long cultivated science as a component of national culture, while the socialist ČSAV had placed scientific work inside a state-directed structure whose public mission was ideologically prescribed. After 1989, the restored principle of academic freedom required a sharp break with political tutelage, and this break was essential for the credibility of Czech science. However, autonomy alone could not provide a sufficient institutional narrative forever. In a democratic system, publicly funded research must continuously articulate why freedom of inquiry matters for society as a whole. The Academy had to avoid two opposite dangers: being absorbed into short-term governmental utility on the one hand, and appearing as an isolated corporative body on the other. Strategy AV21 was one way of holding these two dangers apart by presenting autonomy and social usefulness as complementary rather than contradictory values.

The Academy's need for a new format was also connected with the changing political economy of research after 1993. The post-socialist research system increasingly operated through project competition, grant agencies, international benchmarks, bibliometric indicators, and policy expectations associated with innovation. These mechanisms pushed institutes towards

measurable outputs, but they did not automatically create a coherent national research agenda. Individual teams could be excellent, individual institutes could be productive, and yet the Academy as a whole could still struggle to present a unified public profile. Strategy AV21 addressed precisely this gap between dispersed excellence and institutional visibility. It offered a framework in which the Academy could show not only that its institutes performed high-level research, but also that their work could be coordinated around broad challenges requiring long-term intellectual investment. In this sense, the strategy was not merely an administrative instrument; it was a form of institutional self-description adapted to a new research environment (*Czech Academy of Sciences, 2016*; *Czech Academy of Sciences, 2017*).

The problem was intensified by the internal structure of the Academy itself. AV ČR is not a university with faculties, students, and a unified teaching mission, nor is it a sectoral research agency organised around one policy field. It is a network of highly specialised public research institutes, each with its own disciplinary traditions, leadership, research culture, and international links. This decentralised structure gives the Academy considerable scientific strength, because it protects expert communities and allows them to develop long-term research programmes. At the same time, it makes institutional coordination difficult, especially when social problems do not respect the boundaries between physics, biology, sociology, history, computer science, medicine, linguistics, law, and environmental research. Strategy AV21 responded to this structural difficulty by creating a programme-based layer above individual institutes without abolishing their autonomy. It was therefore a strategic format designed for an academy composed of strong institutes rather than for a centralised research bureaucracy.

The wider transformation of science also made such a format necessary. Since the late 20th century, research policy has increasingly emphasised the production of knowledge in contexts of application, interaction with stakeholders, and responsiveness to uncertain social environments. The influential discussions of “Mode 2” knowledge production, the “triple helix” of university–industry–government relations, and the public value of research did not mean that basic science had disappeared. Rather, they showed that the social organisation of research had become more porous, more collaborative, and more exposed to public evaluation (*Gibbons et al., 1994*; *Nowotny et al., 2001*; *Etzkowitz & Leydesdorff, 2000*; *Bozeman, 2007*). The Czech Academy could not ignore this shift, especially after the Czech Republic’s integration into the European Research Area. A classical academy organised mainly around disciplinary excellence needed a language through which it could participate in this broader transformation without losing its identity. Strategy AV21 supplied such a language by connecting top-level research with public interest.

This did not mean that the Academy suddenly became an applied research organisation in a narrow sense. On the contrary, the official formulation of Strategy AV21 explicitly preserved the centrality of basic research as the foundation of scientific development. The novelty lay elsewhere: in the effort to make basic research visible as a source of long-term solutions, intellectual preparedness, and societal resilience. Contemporary challenges such as climate change, energy transition, demographic ageing, digital vulnerability, public health crises, food security, disinformation, cultural memory, and technological sovereignty cannot be solved by immediate application alone. They require deep knowledge, theoretical imagination, historical understanding, experimental capacity, and interdisciplinary translation. Strategy AV21 therefore allowed the Academy to argue that fundamental science was not remote from public

interest, but one of its most durable conditions. This was a crucial repositioning of the Academy's public image (*Czech Academy of Sciences, 2017*).

The timing of Strategy AV21 was significant. The programme framework was completed at the end of 2014, and the Academy Assembly approved it in December of that year. The first stage began with fourteen research programmes, ranging from the digital era and nuclear power systems to health, ecosystems, public policies, communication, memory, and European statehood. This initial set already revealed the underlying institutional ambition: to show that the Academy's research spectrum could be reorganised around problems that were both scientifically complex and publicly recognisable. The selection of themes also demonstrated that Strategy AV21 was not limited to technology or industrial innovation. It included social sciences and humanities from the beginning, which was essential for avoiding a reduced understanding of public interest as merely economic usefulness. The Academy thus framed contemporary challenges as intellectual, cultural, political, environmental, and technological at the same time (*Czech Academy of Sciences, 2015*).

This breadth was especially important in the Czech context, where the history of the Academy had repeatedly been shaped by the relation between science and national society. During the national revival, scholarly work had helped to construct cultural identity, language, historical memory, and the symbolic infrastructure of the Czech nation. Under socialism, science had been subordinated to a state ideology that claimed to represent collective progress, while often restricting intellectual freedom. After 1989, the Academy had to rebuild trust by distancing itself from ideological control and re-establishing international standards. Strategy AV21 represented a further stage in this long history. It suggested that public responsibility could no longer be understood as obedience to the state, nor as a romantic national mission, but as expert engagement with the complex problems of an open society. In this way, the strategy transformed an older tradition of service to society into a democratic and interdisciplinary form.

The financial and political environment also encouraged the Academy to sharpen its public argument. Annual reporting from the mid-2010s stressed that institutional funding formed only a limited part of the Academy's total budget and that Czech public research operated under pressure to prove efficiency and relevance. In such circumstances, a research institution cannot rely solely on inherited prestige. It must demonstrate why stable support for long-term research is not a privilege, but a public investment. Strategy AV21 helped the Academy make this case by presenting research programmes that were legible to policymakers, entrepreneurs, public institutions, and citizens. The Academy could point to energy, health, public policy, natural hazards, materials, food, digitalisation, and memory as areas where its institutes generated knowledge with social significance. The strategy therefore functioned partly as a defence of institutional funding, but it did so by expanding the language of responsibility rather than by retreating into corporate self-protection (*Czech Academy of Sciences, 2016*).

The new strategic format also answered a communication problem. Modern academies cannot assume that society automatically understands the value of specialised research. The more advanced science becomes, the more difficult it is for non-specialists to see the connection between a laboratory, an archive, a field station, a mathematical model, a linguistic corpus, or a historical edition and their own lives. Strategy AV21 created a bridge between expert work and public intelligibility. Its programmes gave names, narratives, and thematic

frames to research that might otherwise remain hidden inside institute reports and disciplinary journals. This did not simplify the science itself, but it made its public meaning easier to communicate. The strategy thus became a device of scientific translation: not translation from Czech into English or from theory into popularisation only, but translation from institutional complexity into social visibility.

The Academy also needed a framework capable of encouraging cooperation across institute boundaries. In a conventional academy, institutes often build their strength by deepening specialisation. This is intellectually productive, but it can also create silos. Climate research may require atmospheric physics, ecology, economics, legal analysis, and social behaviour; digitalisation may involve computer science, ethics, psychology, linguistics, security studies, and political communication; health research may connect molecular biology, epidemiology, demography, medical technologies, and public policy. A strategic format based on programmes made it possible to organise such connections without dissolving the disciplinary bases on which they depended. Strategy AV21 therefore did not replace institutes with programmes; it overlaid the institute structure with a collaborative matrix. This matrix was one of the main institutional innovations of the strategy (*Czech Academy of Sciences, 2017*).

The programme-based format was also more flexible than a traditional long-term institutional plan. The official materials emphasised that programmes could be adjusted according to interim results, new societal needs, and the attained level of knowledge. This flexibility mattered because contemporary challenges change faster than classical institutional structures. A rigid academy can protect continuity, but it may respond too slowly to emergent problems. A purely project-based system can react quickly, but it may lack depth and stability. Strategy AV21 attempted to combine both qualities: the long-term capacities of Academy institutes and the adaptive logic of thematic programmes. This combination gave AV ČR a way to remain recognisably academic while becoming more strategically responsive.

The five-year programme logic also introduced a moderate form of strategic discipline. Programmes were not simply informal networks or occasional cooperation between friendly researchers. They required coordination, approval, reporting, evaluation, and institutional support. The role of coordinators was especially important because they connected research teams, institute directors, Academy leadership, public communication, and external partners. In this respect, Strategy AV21 created a new layer of academic leadership. It did not only rely on directors of institutes or disciplinary authorities, but also on researchers capable of synthesising problems across fields and presenting them to wider audiences. Such figures became mediators between scholarship, management, and public relevance. The Academy therefore needed Strategy AV21 not only as a plan, but as a mechanism for cultivating new forms of institutional agency.

The strategy was also a response to the growing expectation that research institutions should cooperate with universities, public administration, industry, and international partners. The post-1989 Academy had already developed many such links, but Strategy AV21 made them more visible and programmatic. Its programmes were open to partners beyond the Academy, including universities, businesses, governmental and regional administration, foreign research groups, and public-sector organisations. This openness was not a marginal feature; it was central to the strategy's attempt to define public-interest research. The Academy's knowledge was to remain scientifically independent, but it was not to remain socially enclosed. The new format gave institutional legitimacy to cooperation without making cooperation synonymous

with subordination to external demand (*Czech Academy of Sciences, 2015*; *Czech Academy of Sciences, 2017*).

This balance was delicate because the Academy had to protect its basic research culture. In many countries, the rhetoric of innovation has sometimes reduced science to short-term economic output. For an academy with strong traditions in mathematics, physics, biology, history, philology, philosophy, archaeology, and social research, such a reduction would have been intellectually damaging. Strategy AV21 avoided this danger by using the phrase "top research in the public interest" rather than "applied research for the market". The formula was broad enough to include technology transfer, industrial cooperation, and practical application, but it was also broad enough to include cultural memory, democratic governance, communication, identity, and historical understanding. This semantic choice was institutionally important. It allowed the Academy to engage with innovation policy while preserving a richer conception of public value.

The public-interest formula also helped the Academy distinguish itself from universities. Czech universities are central to education, professional training, and a large part of national research. The Academy, however, is primarily a research institution with concentrated capacities for long-term inquiry. Its public role therefore cannot be explained through teaching alone, although Academy researchers are often connected with doctoral education and university cooperation. Strategy AV21 gave the Academy a distinct public identity: not a university, not a ministry, not a grant agency, not a commercial laboratory, but a national knowledge institution capable of mobilising specialised research for major societal questions. This identity strengthened the Academy's position within the Czech research and innovation system. It also helped explain why a separate academy remained necessary in the 21st century.

The strategy further responded to the problem of fragmentation between excellent research and national priorities. Modern research policy often asks institutions to contribute to strategic priorities, but the priorities themselves can be broad, unstable, or politically formulated. The Academy needed a way to engage with national priorities without becoming merely an executor of policy documents. Strategy AV21 did this by interpreting social relevance through the Academy's own research capacities. Programmes were designed in relation to trends in world science, social relevance, and national priorities of oriented research, experimental development, and innovation, but their scientific content remained grounded in the institutes. In this sense, the strategy was neither a top-down political plan nor a loose catalogue of existing projects. It was a negotiated format through which the Academy translated public priorities into researchable intellectual agendas (*Czech Academy of Sciences, 2017*).

The need for such translation was especially visible in fields where public problems are intellectually complex but politically urgent. Energy policy, for example, cannot be reduced to engineering, because it also involves risk, regulation, economics, public trust, environmental consequences, and geopolitical vulnerability. Public health cannot be reduced to biomedicine, because it also includes demography, behaviour, communication, inequality, and institutional preparedness. Digital transformation cannot be reduced to computer science, because it affects labour, education, privacy, democracy, language, media, and culture. Cultural memory cannot be reduced to heritage preservation, because it shapes identity, conflict, public debate, and the interpretation of political experience. Strategy AV21 allowed the Academy to organise

research around precisely these hybrid problems. It recognised that the most important public questions are rarely owned by a single discipline.

The creation of Strategy AV21 should therefore be read as part of the Academy's broader modernisation after the post-socialist transition. Earlier reforms had concentrated on legal status, governance, evaluation, funding, internationalisation, and the restructuring of institutes. By the 2010s, however, the challenge had shifted towards strategic articulation. The Academy had to show how its dispersed capacities formed a coherent answer to the 21st century. This was a different type of reform: less dramatic than institutional dissolution or legal transformation, but perhaps more subtle in its long-term consequences. It changed how the Academy spoke about itself, how it organised cooperation, and how it presented the relationship between fundamental research and social need. Strategy AV21 was therefore a reform of institutional imagination as much as of research management.

The strategy also reflected an awareness that public trust in expert institutions could no longer be taken for granted. Across Europe, the early 21st century brought new forms of scepticism towards elites, science, media, and state institutions. The expansion of digital communication increased access to knowledge, but also accelerated misinformation, polarisation, and distrust. In such a climate, academies could not limit themselves to producing knowledge for specialist communities. They had to participate more actively in explaining evidence, uncertainty, method, and the social meaning of expertise. Strategy AV21 did not solve this problem by itself, but it gave the Academy a stronger basis for public communication. It made the Academy's research easier to connect with questions that citizens could recognise as part of their own world.

At the same time, Strategy AV21 was not a public-relations campaign detached from research substance. Its credibility depended on the real scientific capacities accumulated inside Academy institutes over decades. Without strong institutes, laboratories, archives, field research, theoretical schools, instrumentation, and expert communities, the strategy would have been only a slogan. The point was not to invent public relevance artificially, but to reveal and organise relevance that already existed in many parts of the Academy. This is why the strategy could include both advanced materials and historical memory, both diagnostics and public policy, both digital risks and communication. It drew from the Academy's existing breadth and gave that breadth a strategic architecture. The new format therefore depended on continuity as much as on innovation.

The Academy also needed Strategy AV21 because the older distinction between "basic" and "applied" research was becoming increasingly insufficient. Many of the most valuable scientific contributions begin as fundamental inquiry and only later acquire practical significance. Conversely, many applied challenges force researchers to rethink basic concepts, methods, and models. A rigid separation between curiosity-driven research and social usefulness can therefore misrepresent how science actually develops. Strategy AV21 offered a more integrated understanding. It suggested that research could be excellent, fundamental, interdisciplinary, and publicly relevant at the same time. This was particularly important for defending the Academy's role against simplistic policy expectations that equated relevance only with immediate commercialisation.

The public-interest orientation also had an ethical dimension. To say that research is conducted in the public interest is to make a claim about responsibility, not only utility. It implies that scientific institutions must consider the quality of life of future generations, the

resilience of society, the sustainability of technological development, the preservation of cultural memory, and the capacity of citizens and policymakers to make informed decisions. This does not mean that researchers should become political actors in a partisan sense. It means that the Academy's independence carries obligations towards the society that sustains it. Strategy AV21 articulated these obligations in a form compatible with academic freedom. It offered a civic vocabulary for scientific autonomy.

The strategy's early reception also showed why the new format mattered institutionally. Official annual reporting noted positive responses from governmental, business, and international circles, as well as interest from foreign partners and inspiration for similar programmes elsewhere. Such responses were important not because they replaced scholarly evaluation, but because they demonstrated that the Academy had found a public language intelligible beyond its own walls. The Academy could speak simultaneously to researchers, policymakers, entrepreneurs, public institutions, and citizens. This multivocal capacity is essential for a modern academy. A research institution that speaks only to itself may remain scientifically productive, but it risks losing strategic influence. Strategy AV21 strengthened the Academy's ability to act as a recognised national knowledge actor (*Czech Academy of Sciences, 2015*; *Czech Academy of Sciences, 2016*).

Another reason the Academy needed the strategy was generational. A national research institution must create conditions not only for current outputs, but also for future scientific communities. Young researchers enter an environment shaped by funding pressures, international mobility, precarious career stages, and competition for recognition. Strategy AV21 could not by itself solve the career problem, but it could help create broader intellectual contexts in which younger researchers saw their work connected to significant public questions. Interdisciplinary programmes can open new spaces for collaboration, visibility, and leadership beyond the narrow hierarchy of individual institutes. They can also show early-career researchers that academic work has social meaning without being reduced to policy service. In this sense, the strategy belonged to the Academy's long-term responsibility for scientific reproduction.

The name "AV21" itself carried symbolic weight. It marked the Academy's attempt to define itself for the 21st century rather than merely to defend its 20th-century inheritance. The number did not signify a complete break with the past, but it indicated a new horizon of self-understanding. The Academy of the 21st century had to be more interdisciplinary, more communicative, more internationally connected, more open to partners, and more capable of addressing uncertainty. Yet it also had to remain an academy: a place where knowledge is pursued with depth, methodological seriousness, and long-term commitment. Strategy AV21 expressed this dual movement. It modernised the Academy without asking it to abandon the academic principle.

The strategy was therefore necessary because the Academy's environment had become too complex for classical institutional self-presentation alone. A catalogue of institutes could not adequately express the Academy's capacity to address society's major challenges. A list of publications could not fully show why public research matters. A set of disciplinary achievements could not by itself explain how knowledge contributes to national resilience, democratic culture, technological development, environmental responsibility, and human self-understanding. Strategy AV21 offered a way to assemble these dispersed meanings into a coherent public mission. It did not replace evaluation, funding reform, international

cooperation, or institute autonomy. Rather, it connected them within a broader institutional narrative.

The need for a new strategic format can finally be understood as the need to redefine the social contract between the Academy and the society it serves. In the socialist period, that contract had been distorted by political ideology and state control. In the early post-socialist period, it was rebuilt through autonomy, reform, and reintegration into international science. In the 21st century, it had to be renewed through public relevance, interdisciplinary cooperation, and responsibility for future challenges. Strategy AV21 was the Academy's answer to this renewal. It declared that high-quality research and public interest were not competing principles, but mutually reinforcing dimensions of a modern academy. This was the institutional rationale from which the later thematic programmes, collaborative governance structures, and public communication practices of Strategy AV21 would develop.

Thus, the Czech Academy of Sciences needed Strategy AV21 because the historical conditions of its legitimacy had changed. The Academy could no longer rely only on the authority of tradition, the prestige of disciplinary excellence, or the memory of post-1989 reform. It had to demonstrate that an autonomous academy of specialised institutes could also function as a strategic national knowledge institution. Strategy AV21 supplied the organisational and symbolic format for this demonstration. It preserved the centrality of basic research, but placed it within a broader horizon of public responsibility. It respected institute autonomy, but created mechanisms for programme-based cooperation. It spoke the language of excellence, but connected excellence with social challenges, policy relevance, innovation, cultural memory, and the quality of life of future generations. In this sense, Strategy AV21 marked not a departure from the Academy's identity, but its adaptation to the intellectual, political, and civic demands of the 21st century.

2. The Idea of "Top Research in the Public Interest"

The motto of Strategy AV21, "Top research in the public interest", condensed into one phrase a major institutional reorientation of the Czech Academy of Sciences. It was deliberately more ambitious than a conventional statement about scientific excellence, because excellence alone did not explain why an academy of publicly funded institutes should remain central to national life. It was also broader than a simple promise of practical usefulness, because the Academy did not want to reduce itself to a service laboratory for immediate governmental or industrial demand. The formula brought together two claims that are often treated separately: that research must be of the highest scientific quality, and that such research must be connected with the long-term interests of society. In this sense, the motto was not a decorative slogan but a compact theory of the Academy's modern mission. It suggested that the public value of science depends precisely on its intellectual strength, methodological depth, and freedom from short-term political or market pressures. Strategy AV21 therefore turned the Academy's traditional defence of autonomy into a more active public argument (*Czech Academy of Sciences, 2017*).

The phrase "top research" carried a specific institutional meaning. It referred to research evaluated according to international standards, embedded in global scholarly networks, and capable of contributing to the development of knowledge beyond national borders. For the Academy, this was essential because its post-1989 legitimacy had been rebuilt through

internationalisation, peer review, competition, and reintegration into European science. However, Strategy AV21 did not present excellence as a closed academic value belonging only to specialist communities. It argued that high-quality research is valuable to society precisely because it produces knowledge that is more reliable, more cumulative, and more resistant to improvisation than politically convenient expertise. In other words, the public interest is not served by weak science that merely speaks in accessible language. It is served by strong science that can withstand scrutiny and then be translated responsibly into public meaning.

The second half of the formula, "in the public interest", was equally significant. It did not mean that every research result had to be immediately useful, profitable, or applicable to a current administrative problem. Rather, it pointed to a broader horizon of social responsibility. Public interest includes health, security, environment, cultural memory, democratic governance, technological development, social cohesion, quality of life, and the capacity of future generations to make informed decisions. Such interests are rarely reducible to short-term indicators. They are often uncertain, contested, and historically evolving. Strategy AV21 therefore used the language of public interest to defend research as a long-term civic resource, not merely as an instrument of economic competitiveness (*Bozeman, 2007*; *Czech Academy of Sciences, 2017*).

This understanding was especially important for a national academy with strong traditions in both the natural sciences and the humanities. A narrow innovation policy might have privileged only those fields that promise patents, products, or industrial partnerships. Strategy AV21 avoided this reduction by placing cultural, social, historical, linguistic, and philosophical research within the same public-interest horizon as energy, materials, medicine, biotechnology, and digital technologies. This was not an accidental inclusiveness. It reflected the Academy's conviction that modern societies need more than technological capacity. They also need historical orientation, cultural self-understanding, legal and political analysis, ethical reflection, and communication across social divisions. The motto therefore preserved the full disciplinary breadth of the Academy and gave that breadth a common public vocabulary.

The idea of public-interest research also marked a clear departure from the socialist understanding of science as service to the state. In the Czechoslovak Academy of Sciences, public purpose had often been defined from above, through ideological planning and political priorities. After 1989, the new Academy had to reclaim autonomy from that legacy. Yet by the 2010s, it was no longer enough simply to say that science must be free from political control. The more difficult task was to show how autonomous science can still be socially responsible. Strategy AV21 answered this question by separating public interest from state command. It implied that the Academy may serve society not by obeying the political regime, but by producing independent, high-quality knowledge on problems that matter to citizens, institutions, and future generations.

This distinction is crucial for understanding the democratic character of Strategy AV21. A democratic society cannot demand that science merely confirm governmental preferences, but it can expect publicly funded science to engage with shared problems. The Academy's independence is therefore not a withdrawal from society; it is a condition for more trustworthy service to society. Research on climate change, health risks, public policy, technological security, or cultural memory loses much of its value if it is shaped by partisan convenience. Conversely, it gains public significance when it is able to speak from a position of

methodological independence. The motto “Top research in the public interest” expressed this delicate balance between distance and engagement.

The formula also helped the Academy avoid the false opposition between basic and applied research. In public debates, basic research is sometimes portrayed as intellectually prestigious but socially remote, while applied research is viewed as useful but less fundamental. Strategy AV21 implicitly rejected this division. It showed that many societal challenges require precisely the kind of long-term knowledge that only basic research can provide. New materials, gene therapy, energy systems, environmental modelling, artificial intelligence, language technologies, demographic analysis, and the study of collective memory all depend on accumulated theoretical, empirical, and methodological work. The Academy therefore presented public interest not as a constraint imposed on basic research, but as one of the contexts in which the value of basic research becomes visible.

At the same time, the motto did not dissolve the difference between scientific knowledge and political decision-making. The Academy could provide evidence, models, concepts, scenarios, and expert interpretation, but it could not replace democratic choice. This separation was important because public-interest science must not become technocracy. Strategy AV21 placed the Academy in a position of responsibility, not sovereignty. Its task was to strengthen the knowledge base of society, not to govern society in the name of expertise. Such a position requires intellectual modesty as well as scientific confidence. The Academy had to present itself as a strategic knowledge institution while recognising that science participates in public life alongside law, politics, civil society, culture, and ethical debate.

The idea of public interest also expanded the meaning of innovation. In a narrow economic sense, innovation is often associated with commercialisation, technology transfer, competitiveness, and industrial renewal. Strategy AV21 included these dimensions, but it did not allow them to monopolise the Academy’s mission. Innovation could also mean new ways of understanding risk, new methods of public communication, new models of social policy, new forms of heritage interpretation, new diagnostic capacities, or new tools for environmental adaptation. This broader understanding suited the Academy because its institutes produced many kinds of knowledge, not all of which entered the market directly. Public-interest research therefore widened the conceptual space in which academic innovation could be recognised (*Etzkowitz & Leydesdorff, 2000*; *Czech Academy of Sciences, 2017*).

This broadness was also visible in the early programme structure of Strategy AV21. The first programmes included themes such as the digital age, efficient energy conversion, natural hazards, new materials, quality of life and health, food for the future, systems for nuclear power, memory, effective public policies, forms of communication, and Europe and the state. These titles already show that the Academy understood public interest as a multidimensional field. It was not only a matter of laboratories and technologies, but also of political institutions, communication, cultural continuity, and social resilience. Such a programme structure gave practical institutional form to the motto. It translated an abstract principle into coordinated research areas.

The phrase “top research” also served as a safeguard against populist interpretations of public interest. Public interest is not identical with immediate public opinion, media attention, or political popularity. Scientific work may be in the public interest even when its significance is not immediately understood by the broader public. Conversely, research can be publicly visible without being scientifically robust. Strategy AV21’s formula protected the Academy

from both dangers by insisting that social relevance must rest on scholarly quality. The public has a legitimate interest not merely in research that sounds useful, but in research that is actually competent, rigorous, and capable of producing dependable knowledge.

This point is particularly important in the age of digital misinformation and declining trust in expert institutions. Public communication has become faster, more fragmented, and more vulnerable to manipulation. In such an environment, research institutions cannot remain silent, but they also cannot compete with misinformation by abandoning complexity. Strategy AV21's public-interest orientation encouraged the Academy to become more visible while maintaining scientific seriousness. It gave public communication a stronger institutional foundation. The Academy could explain its research not as isolated curiosity, but as part of a structured effort to address problems that affect everyday life, public policy, cultural identity, and national resilience.

The motto also expressed a shift from passive availability of expertise to active agenda formation. A classical academy may wait to be consulted by ministries, universities, cultural institutions, or the public. Strategy AV21 encouraged the Academy to formulate research programmes proactively. It identified areas where the Academy believed its capacities could contribute to society before a crisis or administrative request defined the problem too narrowly. This proactive role was important because many contemporary challenges require preparedness rather than reaction. Public-interest research must often anticipate risks, build knowledge infrastructures, and maintain expert communities before their necessity becomes obvious.

The connection between public interest and long-term preparedness was especially relevant in fields such as public health, energy, environment, security, and digitalisation. Societies frequently discover the value of expertise only when a crisis occurs. Yet by that time, the necessary research capacities must already exist. The Academy's institutes preserve precisely such capacities: laboratories, databases, archives, field stations, collections, models, instruments, and specialist communities. Strategy AV21 made this latent preparedness more visible. It showed that public-interest science is not only the science that solves today's problem, but also the science that keeps society intellectually prepared for tomorrow's uncertainties.

The same logic applied to the humanities and social sciences. Historical research, philosophy, philology, sociology, economics, law, psychology, and political science may not always produce immediately tangible outputs, but they shape the interpretative resources of society. They help citizens and institutions understand memory, identity, conflict, inequality, legitimacy, communication, and social change. In times of democratic stress, such knowledge is not decorative. It becomes part of the intellectual infrastructure of public life. Strategy AV21's inclusion of social and human sciences therefore prevented the public-interest idea from becoming technologically one-sided. It affirmed that societies need meaning, memory, and judgement as well as innovation.

The formula also helped redefine the Academy's relationship with the state. The Academy remained a public research institution supported by public resources, and therefore it had obligations towards the national community. But Strategy AV21 framed this relationship as partnership rather than subordination. Research programmes were open to cooperation with state and regional administration, but their intellectual logic came from the Academy's scientific capacities. This allowed AV ČR to contribute to public policy without becoming an

administrative department. The public interest was therefore mediated through expertise, collaboration, and programme design, not through direct political control.

The relationship with industry was similarly nuanced. Strategy AV21 recognised that public-interest research may generate technologies, methods, prototypes, and applications relevant to business and production. However, industrial usefulness was not treated as the only measure of value. The Academy's cooperation with business had to remain compatible with scientific quality, openness, and longer-term societal benefit. This was important because some research areas, such as energy transition, advanced materials, food systems, biomedical technologies, and artificial intelligence, lie at the intersection of public need and economic opportunity. Strategy AV21 gave the Academy a framework for entering this intersection without reducing its mission to commercial service.

The motto also strengthened the Academy's role in the European research environment. European research policy increasingly emphasised grand challenges, responsible research and innovation, interdisciplinarity, societal impact, and cooperation across sectors. Strategy AV21 allowed the Czech Academy to speak this European language while retaining a distinct national institutional identity. It was not merely copying European terminology; it was translating the Academy's own historical and disciplinary capacities into a form compatible with the European Research Area. This was particularly important for an institution that had rebuilt itself after the end of state socialism and now needed to operate confidently within transnational research structures. The public-interest formula thus had both domestic and European significance (*European Commission, 2012*; *Owen, Macnaghten, & Stilgoe, 2012*).

The idea of "top research in the public interest" also implied a new style of institutional storytelling. The Academy could no longer be presented only as a collection of institutes founded in different periods and devoted to different disciplines. It needed narratives that showed why these institutes belonged together. Strategy AV21 provided such narratives through programmes that cut across institutional boundaries. A physicist, a biologist, a historian, a sociologist, and a computer scientist could all appear as contributors to shared public questions. This did not erase disciplinary identity, but it gave the Academy a more integrated public image. The motto therefore helped transform institutional plurality into strategic coherence.

The public-interest principle was particularly useful because it allowed the Academy to speak to multiple audiences at once. To scientists, it said that excellence remained non-negotiable. To policymakers, it said that the Academy could contribute to national priorities and long-term decision-making. To citizens, it said that academic research was not detached from everyday concerns. To business and public institutions, it said that cooperation with the Academy could generate knowledge of practical value. To the international community, it said that Czech science was engaged with global challenges. A successful institutional formula must be capable of such multiple translation, and Strategy AV21 achieved this more effectively than a purely internal strategic plan would have done.

However, the formula also contained a demanding promise. To claim public-interest research is to accept responsibility for relevance, communication, and accountability. The Academy had to show that its programmes were not merely rebranded existing projects, but real attempts to connect expertise with significant challenges. This required coordination, reporting, public presentation, and continuing adjustment of programme themes. It also required researchers to think beyond the immediate boundaries of their specialisms without

compromising scientific depth. Strategy AV21 therefore placed new expectations on the Academy's internal culture. The motto was inspiring, but it was also institutionally binding.

The concept of public interest also raised the problem of selection. No research institution can address every social challenge, and no academy can define the public interest in a complete or final way. Strategy AV21 therefore had to choose themes where the Academy possessed real capacities and where the problems were sufficiently broad, urgent, and intellectually demanding. This selective character was important. It prevented the strategy from becoming a vague declaration that all science is useful in some unspecified sense. Public-interest research required prioritisation, but prioritisation had to be based on the intersection of scientific strength, social relevance, and long-term strategic need.

The motto also had an internal integrative function. Institutes of the Academy differ greatly in scale, methods, audiences, and traditions. Some work with large instruments and experimental facilities; others with texts, archives, social data, mathematical models, biological systems, or field observation. Without a common strategic language, such diversity can appear fragmented. "Top research in the public interest" allowed these different research cultures to recognise themselves within a shared institutional mission. It did not force them into uniformity. Instead, it offered a flexible formula in which many forms of excellence could be connected to many forms of public value.

This flexibility was one of the reasons the motto proved durable. A narrower slogan might have become obsolete as policy priorities changed. Public interest, however, can accommodate changing problems while preserving a stable institutional orientation. In one period, energy security and digitalisation may dominate; in another, public health, climate adaptation, artificial intelligence, or social resilience may become more prominent. The formula allows programmes to evolve without abandoning the underlying mission. This adaptability was essential for Strategy AV21 because the Academy was not designing a one-time campaign, but a strategic framework for the 21st century.

The phrase also conveyed a moral argument about public funding. Public resources invested in research should not be understood simply as expenditure, nor even only as investment in competitiveness. They are also investments in collective intelligence. A society that supports high-quality research increases its capacity to understand itself, adapt to change, manage risk, preserve memory, and imagine alternatives. Strategy AV21 gave the Academy a way to express this argument without sounding defensive. It did not ask society to support the Academy because the Academy had always existed. It asked society to recognise that a modern democratic state needs independent institutions capable of producing knowledge for the common good.

In this respect, Strategy AV21 belongs to a broader tradition of thinking about science as a public good. Scientific knowledge often exceeds the interests of the individual researcher, the single institute, the immediate funder, or the present generation. It circulates, accumulates, and creates unforeseen possibilities. At the same time, it requires institutions capable of sustaining work whose value may not be instantly measurable. The Academy is one such institution. The motto "Top research in the public interest" therefore linked the Academy's practical strategy with a deeper philosophy of knowledge. It affirmed that advanced research is part of the infrastructure of a civilised society (*Merton, 1973*; *Polanyi, 1962*).

The idea was also historically resonant in the Czech lands. Czech scientific institutions had long been intertwined with questions of language, education, culture, modernisation, and

national self-definition. Yet Strategy AV21 reinterpreted this tradition in a contemporary democratic form. Public interest was no longer defined primarily as national awakening, ideological progress, or institutional survival. It was defined through open-ended engagement with social, technological, environmental, cultural, and economic challenges. This made the Academy's public mission less monumental but more practical, less rhetorical but more structurally embedded. It showed how an institution with deep historical roots could speak to the conditions of the 21st century.

Thus, the idea of "top research in the public interest" became the conceptual centre of Strategy AV21 because it reconciled values that the Academy needed to hold together: excellence and responsibility, autonomy and engagement, basic research and practical relevance, disciplinary depth and interdisciplinary cooperation, national service and international science. The formula allowed AV ČR to present itself not as a relic of the classical academy, nor as a purely applied research agency, but as a strategic public knowledge institution. It protected the dignity of fundamental research while making its social meaning more visible. It expanded innovation beyond the market and public service beyond state command. Most importantly, it gave the Academy a new language of legitimacy: the Academy exists because society needs independent, high-quality, long-term research capable of addressing the problems, uncertainties, memories, and possibilities that define public life.

3. Strategy AV21 as a Response to Contemporary Challenges

Strategy AV21 was not conceived in a historical vacuum, nor was it merely an internal reform of research administration. Its deeper significance lay in the fact that it translated the Academy's institutional capacities into a response to the major uncertainties of the 21st century. By the mid-2010s, the Czech Academy of Sciences was operating in a world in which scientific institutions were expected not only to generate knowledge, but also to help societies understand risk, complexity, acceleration, and vulnerability. Climate change, energy transition, technological disruption, demographic ageing, health insecurity, food systems, public mistrust, geopolitical instability, cultural memory, and digital transformation had become interconnected problems rather than separate policy sectors. A classical academy organised around disciplines and institutes could address each of these questions in specialised ways, but Strategy AV21 created a framework for addressing them as shared civilisational challenges. The strategy therefore represented a move from institutional self-preservation to strategic engagement with the conditions of contemporary life (*Czech Academy of Sciences, 2017*).

The word "contemporary" in the official materials of Strategy AV21 is important because it does not simply mean "current" or "recent". It points to a type of problem characteristic of late modern societies: problems that are complex, uncertain, interdisciplinary, and often global in origin but local in their consequences. Climate change is planetary, yet its effects are experienced through Czech landscapes, water systems, agriculture, forests, urban planning, and energy policy. Digitalisation is global, but it reshapes Czech education, labour, communication, state administration, media, and democratic debate. Public health threats circulate across borders, but they test national institutions, hospitals, laboratories, social trust, and the ability of citizens to understand scientific advice. Strategy AV21 responded to precisely this combination of global interdependence and national responsibility. It gave the

Academy a way to place Czech research within the world's major transformations without losing the specificity of Czech society.

The strategy's response to contemporary challenges must also be understood through the concept of risk. Since the late 20th century, social theory has described modern societies as increasingly preoccupied with risks produced by modernisation itself: technological systems, environmental degradation, industrial side-effects, nuclear infrastructures, financial volatility, and the uncertain consequences of scientific progress (*Beck, 1992*). Strategy AV21 did not use this sociological vocabulary as its primary language, but its programme structure clearly reflected a similar awareness. It included nuclear systems, natural hazards, energy conversion, digital risks, health, ecosystems, food, public policies, communication, and memory. These themes all point to areas where society needs knowledge not only to advance, but also to avoid harm. In this respect, Strategy AV21 interpreted science as a resource for anticipation, prevention, adaptation, and informed decision-making.

The Academy's response to contemporary challenges was therefore not limited to crisis management. It was more ambitious and more patient. Crises reveal weaknesses dramatically, but the knowledge required to face them must be built long before they occur. Laboratories, observatories, archives, long-term data series, linguistic corpora, biological collections, field stations, experimental facilities, social surveys, and historical expertise cannot be improvised in the moment of danger. Strategy AV21 made this long-term preparedness visible. It showed that the Academy's public value lay not only in immediate advice during emergencies, but also in maintaining the intellectual infrastructure that allows society to understand emerging problems before they become disasters. This is one of the strongest arguments for a national academy in the 21st century.

Energy was one of the clearest examples of this new logic. The Czech Republic, like other European countries, faced the problem of securing reliable, affordable, and environmentally responsible energy while responding to climate obligations, technological change, and geopolitical vulnerability. Strategy AV21's early programmes on nuclear power systems, efficient energy conversion and storage, and later sustainable energy themes connected physics, engineering, materials science, environmental research, safety analysis, and social considerations. Such a combination was necessary because energy policy is never only a technical question. It involves infrastructure, risk perception, industrial capacity, public trust, environmental burden, international dependency, and long-term investment. The Academy's role was not to replace political decision-making, but to provide the knowledge base without which such decision-making becomes short-sighted or ideological (*Czech Academy of Sciences, 2017*).

Environmental and climate-related challenges required an equally broad scientific response. The Strategy AV21 framework recognised that landscapes, ecosystems, biodiversity, natural hazards, soil, water, and atmosphere are interconnected systems shaped by both natural processes and human activity. Czech environmental problems are not abstract examples from global reports; they are visible in droughts, floods, forest degradation, agricultural pressures, urban heat, biodiversity loss, and disputes over land use. The Academy's institutes had long-standing expertise in geology, atmospheric physics, ecology, botany, hydrology, soil science, geography, and environmental law. Strategy AV21 allowed these capacities to be coordinated around issues that mattered for citizens, municipalities, ministries, and future generations. It

thereby transformed environmental knowledge from a set of specialised disciplines into a public-interest research agenda.

The challenge of natural hazards further demonstrated why Strategy AV21 required interdisciplinarity. Floods, storms, droughts, landslides, seismic risks, space weather, and other hazards are not merely physical events. They become social events through settlement patterns, infrastructure, communication, legal responsibility, insurance systems, local administration, public memory, and political preparedness. A natural hazard becomes a disaster when society is unprepared, when information is weak, or when institutions fail to coordinate. Strategy AV21's attention to natural hazards therefore connected earth sciences with social analysis and public administration. This was a modern form of academic responsibility: to understand not only the event itself, but also the conditions under which a society can withstand it.

Health represented another major area in which contemporary challenges demanded a strategic format. By the 2010s, biomedical research was already moving towards molecular diagnostics, personalised medicine, gene therapy, advanced imaging, translational medicine, and data-driven approaches to disease. At the same time, societies were ageing, chronic illnesses were increasing, and public health systems were under growing pressure. Strategy AV21 programmes dealing with wellbeing, diagnostics, pharmaceuticals, precision medicine, and later infectious diseases addressed this complex field from several angles. They linked laboratory science with clinical potential, biological mechanisms with technologies, and health innovation with social need. This was not a shift away from fundamental biomedical research, but a way of showing why such research matters to public life.

The COVID-19 pandemic, although it came after the launch of Strategy AV21, made the rationale of such a programme-based approach even more visible. The pandemic showed that health crises are not purely medical events. They involve virology, immunology, epidemiology, modelling, diagnostics, public communication, trust in science, law, education, social behaviour, economic consequences, and international coordination. Institutions that had already built interdisciplinary channels were better positioned to contribute expertise across these dimensions. Strategy AV21 did not predict the pandemic in a narrow sense, but it embodied the institutional logic that such crises require. It treated public health as an area where basic research, applied technologies, social knowledge, and communication must interact.

Digitalisation was another challenge that made the older disciplinary model insufficient. The digital era produces enormous quantities of data, new forms of communication, algorithmic decision-making, cybersecurity risks, artificial intelligence, digital archives, language technologies, and changes in labour and education. Strategy AV21's early programme on the hopes and risks of the digital era captured this duality very well. Digitalisation promised new knowledge, efficiency, and innovation, but it also brought vulnerabilities: surveillance, misinformation, exclusion, dependence on platforms, data misuse, and the erosion of reliable public debate. The Academy's response therefore had to include mathematics, computer science, information theory, sociology, psychology, linguistics, philosophy, law, and media studies. The challenge was not only to build digital tools, but also to understand the society being transformed by them.

Artificial intelligence intensified this issue in the following decade. AI became a technological, economic, scientific, ethical, and political problem at the same time. It could accelerate

discovery, support diagnostics, improve modelling, and transform industry, but it could also produce bias, opacity, labour disruption, disinformation, and new forms of dependence. Strategy AV21's later development, including programmes connected with artificial intelligence for science and society, showed the flexibility of the framework. The Academy could incorporate new challenges as they emerged, rather than remaining tied to the initial thematic list from 2015. This adaptability was one of the strategy's most important features. It allowed AV ČR to remain intellectually current while relying on long-term research capacities.

Food security and biotechnology provided another field where contemporary challenges crossed scientific and social boundaries. Food for the future is not only a question of agricultural productivity. It involves climate resilience, plant biology, soil quality, water management, microbiology, food chemistry, nutrition, public health, logistics, consumer behaviour, and social inequality. Biotechnology and synthetic biology add further complexity, because they generate both hope and public anxiety. Research on genetically modified organisms, microbial systems, new crops, or food technologies must therefore be accompanied by communication, regulation, ethics, and public understanding. Strategy AV21 created a format in which such issues could be treated as integrated public problems rather than isolated technical tasks.

The challenge of materials and future industries also required a strategic response. Modern economies depend on advanced materials, nanotechnologies, composites, metals, ceramics, semiconductors, optical technologies, sensors, and surface treatments. Such fields require expensive infrastructure, long-term experimentation, and cooperation between fundamental research and industrial application. A purely short-term project system cannot easily sustain this kind of research ecology. Strategy AV21 made it possible to coordinate institutes and external partners around materials as a national strategic capability. This mattered not only for economic competitiveness, but also for energy systems, medicine, transport, defence, space research, environmental technologies, and industrial modernisation. Materials science thus became a bridge between the Academy's experimental traditions and the technological future of the country (*Czech Academy of Sciences, 2017*).

Space research and light-based technologies illustrate the same point from a different angle. These areas might appear highly specialised, even remote from everyday life, but they have practical and strategic implications for communication, observation, instrumentation, medicine, security, climate monitoring, and industrial innovation. Strategy AV21 placed such research within a public-interest framework by showing how advanced scientific capacities can generate societal value in unexpected ways. This is important because public interest is not always obvious at the beginning of a research trajectory. Many technologies that later become socially indispensable originate in highly specialised scientific work. The Academy's task was to preserve the conditions for such work while communicating its broader significance.

Public policy itself became one of the themes of Strategy AV21, and this was institutionally very revealing. The Academy was not concerned only with supplying technical solutions to external decision-makers. It also recognised that policies must be studied, evaluated, compared, and improved through social science. Effective public policy requires evidence on education, labour markets, housing, inequality, taxation, social mobility, ageing, regional development, governance, and institutional trust. By including public policy among its strategic programmes, the Academy asserted that social diagnosis is part of the public-interest mission of science. It

also showed that the social sciences were not secondary to technological research, but essential for understanding how societies actually function.

The programme logic of Strategy AV21 was especially valuable because contemporary challenges are often “wicked problems”. Such problems have no single definition, no final solution, and no purely technical answer. Climate adaptation, public health, migration, digital misinformation, energy transition, social inequality, biodiversity loss, and cultural conflict all involve competing values, incomplete knowledge, institutional complexity, and long-term consequences. Strategy AV21 did not pretend that science could eliminate this complexity. Instead, it positioned the Academy as an institution capable of clarifying it. The Academy could formulate problems more precisely, provide evidence, reveal trade-offs, and offer scenarios. This is a more realistic and more democratic understanding of scientific contribution than the promise of simple solutions.

Cultural memory, heritage, and identity were also treated as contemporary challenges rather than as merely retrospective fields. This is one of the most distinctive features of Strategy AV21 and of the Czech Academy’s broader intellectual profile. In societies marked by the legacies of empire, nationalism, socialism, occupation, normalisation, revolution, European integration, migration, and digital media, memory is not a passive archive. It shapes public debate, identity, legitimacy, conflict, and the interpretation of democratic experience. Programmes on memory, communication, Europe, statehood, global conflicts, and later materiality and identity showed that the humanities can address urgent social questions. The Academy thereby affirmed that the public interest includes the capacity to remember, interpret, and argue responsibly about the past.

Communication was another key area because contemporary societies do not suffer only from a shortage of information. They often suffer from the fragmentation of communication, the loss of shared interpretative frameworks, and the strategic manipulation of language and media. Research on forms and functions of communication, language technologies, media, public discourse, and digital culture therefore belongs directly to the Academy’s response to contemporary challenges. Public interest requires not only facts, but also communicative conditions under which facts can be heard, understood, and debated. The Academy’s linguistic, philosophical, sociological, psychological, and computational capacities could all contribute to this task. Strategy AV21 made such contributions more visible within a unified framework.

Security and resilience formed another layer of the strategy’s response. In the 21st century, security no longer means only military defence. It includes energy security, cyber security, biological safety, food security, environmental resilience, infrastructure protection, social cohesion, and resistance to disinformation. The Academy could not and should not become a security agency, but it could provide knowledge relevant to these broader forms of resilience. Its institutes could analyse risks, model systems, study social vulnerabilities, develop technologies, interpret geopolitical and cultural processes, and contribute to informed public debate. Strategy AV21 thus reflected the expansion of security thinking into a knowledge-intensive field.

The strategy also responded to the changing relationship between science and citizens. Contemporary societies expect scientific institutions to communicate, explain, and sometimes justify their work more actively than in the past. This expectation can be demanding, and it can even become unfair when complex science is forced into oversimplified

public narratives. Yet the expectation itself cannot be ignored. Strategy AV21 gave the Academy thematic frameworks through which it could speak to citizens about research that affects their lives. Instead of presenting disconnected institute achievements, the Academy could discuss health, energy, digitalisation, memory, environment, public policy, and future technologies. This improved the public readability of the Academy's work.

The Academy's response to contemporary challenges was also a response to the Europeanisation of research. European research policy increasingly organised funding and cooperation around grand challenges, missions, societal impact, sustainability, responsible research and innovation, and interdisciplinary consortia. Horizon 2020 and later Horizon Europe strengthened this orientation by linking excellent science with global challenges, industrial competitiveness, and societal missions (*European Commission, 2021*). Strategy AV21 allowed the Czech Academy to align with these European tendencies while preserving its own institutional profile. The Academy was not merely adapting to funding terminology. It was reinterpreting its national role in a European research culture increasingly structured around complex challenges.

This European dimension did not weaken the Academy's national significance. On the contrary, it made the national role more complex. A 21st-century national academy must help its society participate in global knowledge systems and European research networks, but it must also interpret global challenges in relation to national conditions. Strategy AV21 did exactly this. It connected international scientific trends with Czech energy debates, Czech landscapes, Czech health needs, Czech public policy, Czech cultural memory, and Czech technological capacities. The Academy became not only a producer of research, but a mediator between global knowledge and national decision-making.

The strategy's openness to universities, businesses, state administration, regional institutions, foreign research groups, and public-sector organisations was therefore not an accessory. It was part of its response to contemporary challenges. Such challenges cannot be solved inside one institution. They require networks, translation, coordination, and mutual learning between different actors. However, Strategy AV21 also recognised that networks need intellectual anchors. The Academy's institutes provided such anchors through their long-term expertise, specialist communities, and research infrastructures. The strategy thus combined openness with institutional depth.

One of the most important institutional achievements of Strategy AV21 was that it gave the Academy a flexible mechanism for updating its agenda. The initial programme framework of 2015 was later expanded and revised, and new programmes were introduced as new social and scientific questions gained urgency. This flexibility was not a sign of instability. It was a deliberate answer to the changing nature of contemporary challenges. A strategic academy cannot freeze its understanding of public interest at the moment when a plan is adopted. It must remain capable of recognising new risks, new technologies, new cultural tensions, and new forms of vulnerability. Strategy AV21 created the procedural space for such recognition.

At the same time, the strategy did not mean that the Academy abandoned its older research traditions. Its response to contemporary challenges was built on accumulated capacities from earlier periods: strong physical sciences, chemical research, biological and biomedical institutes, mathematical and computational schools, earth sciences, humanities, social sciences, and historical scholarship. The novelty lay in the way these capacities were assembled and publicly interpreted. Strategy AV21 did not create excellence from nothing; it

reorganised excellence into challenge-oriented programmes. This distinction matters because it shows that the strategy was both innovative and conservative in the best sense. It innovated by changing the organisational format, but it conserved the deep research foundations of the Academy.

The strategy also provided a new way of understanding the Academy's responsibility to future generations. Many contemporary challenges unfold over decades: climate change, energy transition, demographic ageing, biodiversity loss, cultural memory, technological dependence, and educational transformation. Political cycles are often too short to address such processes with sufficient continuity. A national academy, by contrast, can maintain long-term research attention across electoral periods and policy fashions. Strategy AV21 explicitly connected research with the quality of life of future citizens. This temporal horizon distinguished the Academy's role from short-term consultancy and made its public-interest mission more profound.

The response to contemporary challenges also required humility. No academy can solve climate change, energy dependence, public mistrust, digital disruption, or health insecurity by itself. Strategy AV21 did not claim such omnipotence. Its more credible claim was that society needs institutions capable of producing reliable knowledge, integrating disciplines, communicating uncertainty, and cooperating with public and private actors. In this sense, the Academy's contribution was not final control over problems, but the strengthening of collective intelligence. This is a less dramatic but more realistic conception of scientific power. It also corresponds better to the democratic role of expertise.

Strategy AV21 therefore transformed the Academy's relationship with application. Application was no longer understood only as the commercial use of a discovery or the implementation of a technology. It also included policy relevance, public understanding, cultural interpretation, risk assessment, diagnostic capacity, educational impact, and preparedness for future crises. This broader notion of application suited an institution whose research spectrum extends from particle physics to medieval studies, from biotechnology to philosophy, from computational modelling to sociology. It allowed different forms of knowledge to contribute to public interest in different ways. The strategy thereby prevented the Academy's public mission from being narrowed to one dominant model of usefulness.

The later development of Strategy AV21 confirmed the durability of this approach. New programmes in areas such as biodiversity, infectious diseases, artificial intelligence, materiality, and identity demonstrated that the framework could absorb emerging challenges while retaining its original logic. The public-interest formula remained stable, but the thematic content evolved. This combination of stability and adaptation is one of the marks of a mature strategic institution. It shows that Strategy AV21 was not merely a response to the problems visible in 2014, but an institutional mechanism for responding to problems as they change over time (*Czech Academy of Sciences, 2026*).

Thus, Strategy AV21 functioned as the Czech Academy of Sciences' answer to the defining challenges of the 21st century because it connected knowledge, responsibility, interdisciplinarity, and public relevance within a single institutional framework. It recognised that contemporary problems are too complex for isolated disciplines, too urgent for passive academic distance, and too long-term for short political cycles. It allowed the Academy to respond to climate change, energy transition, digitalisation, health risks, public policy, technological development, cultural memory, communication, security, and social resilience

without abandoning the centrality of fundamental research. Its significance lay not in replacing classical academic values, but in giving them a new strategic form. The Academy remained an institution of scholarship, but Strategy AV21 enabled it to speak and act as a public-interest research institution prepared to address the uncertainties, risks, and possibilities of contemporary society.

Interdisciplinarity as an Organisational Principle

1. Crossing Boundaries between Institutes and Disciplines

Interdisciplinarity in Strategy AV21 was not a rhetorical ornament added to an otherwise conventional research plan. It was one of the organisational answers to the central difficulty faced by a modern academy composed of highly specialised institutes. The Czech Academy of Sciences had inherited, developed, and reformed a structure in which scientific strength was concentrated in relatively autonomous research workplaces. This structure made it possible to maintain depth, continuity, expert cultures, instrumentation, archives, collections, laboratories, and long-term schools of thought. Yet the same structure could also make the Academy appear fragmented when public challenges required a coordinated response. Strategy AV21 therefore introduced a programme logic that crossed the boundaries between institutes and disciplines without abolishing the institutional foundations on which the Academy's quality depended. Its task was not to weaken specialisation, but to make specialisation communicative, cooperative, and strategically visible (*Czech Academy of Sciences, 2017*).

The need to cross boundaries followed from the nature of the problems Strategy AV21 was designed to address. Energy, climate, health, artificial intelligence, public policy, cultural memory, biodiversity, food systems, security, materials, and communication are not contained within a single discipline. They have physical, biological, technological, social, legal, historical, economic, psychological, and cultural dimensions. A technical solution may fail if social acceptance is ignored; a biomedical innovation may remain ineffective if public communication collapses; environmental policy may be weak if it lacks both ecological data and legal analysis; digital technologies may become socially harmful if ethical and political consequences are neglected. Strategy AV21 therefore recognised that contemporary challenges are not merely large topics, but structurally mixed topics. They require forms of research organisation capable of moving across disciplinary borders while preserving disciplinary competence.

The Academy's institute structure made this task both difficult and promising. It was difficult because institutes often possess their own internal hierarchies, budgetary routines, publication cultures, research priorities, and professional identities. A physicist, a historian, a chemist, a sociologist, a botanist, and a computer scientist may all work within the same academy, but they do not automatically share concepts, evidence standards, temporal horizons, or research languages. At the same time, the structure was promising because the Academy contained a rare concentration of specialised capacities under one institutional roof.

Strategy AV21 could therefore draw on an internal diversity that universities, ministries, or private research organisations might not possess in the same form. The strategy transformed this diversity from a possible source of fragmentation into a resource for public-interest research.

The crossing of institute boundaries was especially important because the Academy was not created as a single disciplinary faculty or a compact research centre. It is an institutional constellation. Its institutes belong to different scientific areas and often have distinct historical genealogies, some rooted in older Czechoslovak scientific schools, others reshaped after 1989, and still others strengthened through European projects and international collaborations. Strategy AV21 did not attempt to erase these genealogies. Instead, it introduced a horizontal layer of cooperation in which institutes could participate according to research capacity and thematic relevance. This horizontal layer allowed the Academy to act more like a strategic network than a collection of separate workplaces. It was a subtle but important change in institutional behaviour.

The programme structure of Strategy AV21 therefore functioned as a bridge between the vertical logic of institutes and the horizontal logic of problems. Institutes remained the basic units of research life, employment, equipment, leadership, evaluation, and disciplinary continuity. Programmes, by contrast, assembled teams across institute boundaries around broader themes. This meant that the Academy did not have to choose between institute autonomy and strategic coordination. It could maintain both, although this balance required careful governance. If coordination became too weak, programmes would be little more than labels. If coordination became too strong, they might threaten the autonomy and creativity of institutes. Strategy AV21 tried to occupy the middle ground between these two extremes (*Czech Academy of Sciences, 2017*).

This middle ground reflected a wider transformation in the organisation of science. Since the late 20th century, scholars of science policy have argued that knowledge production increasingly takes place in contexts where disciplinary boundaries are porous and where social, economic, and political actors interact with research institutions more frequently than before. The idea of “Mode 2” knowledge production, though often debated, captured the growing importance of problem-oriented, transdisciplinary, socially distributed research (*Gibbons et al., 1994*; *Nowotny et al., 2001*). Strategy AV21 can be interpreted as the Academy’s own institutional response to this broader transformation. It did not simply imitate a policy fashion. It adapted the challenge-oriented language of contemporary science to the specific structure and historical role of AV ČR.

The strategy also showed that interdisciplinarity is not the same as generality. Crossing boundaries does not mean that everyone becomes a generalist or that disciplinary expertise loses value. On the contrary, meaningful interdisciplinarity depends on strong disciplines. A climate programme without atmospheric physics, hydrology, ecology, and soil science would be shallow; a digitalisation programme without mathematics, computer science, linguistics, sociology, and law would be incomplete; a memory programme without history, archaeology, literary studies, philosophy, anthropology, and archival expertise would be decorative. Strategy AV21 therefore required disciplines to enter into dialogue from positions of strength. It was not an argument against disciplinary knowledge, but against the isolation of disciplinary knowledge.

This distinction matters because interdisciplinarity is often praised too easily. In practice, it is difficult, time-consuming, and sometimes intellectually uncomfortable. Researchers must learn unfamiliar vocabularies, recognise different standards of evidence, negotiate priorities, and accept that another discipline may define the same problem differently. A biologist may think in terms of organisms, mechanisms, and experimental control; a sociologist may think in terms of institutions, behaviour, and inequality; a historian may think in terms of context, chronology, and interpretation; a computer scientist may think in terms of algorithms, models, and data structures. Strategy AV21 created institutional spaces in which such differences could be worked through rather than ignored. Its significance lay partly in making interdisciplinary cooperation a recognised organisational expectation rather than an exceptional personal initiative.

The Academy's earlier history gave this development particular meaning. Under the socialist ČSAV, interdisciplinarity could be invoked within centrally planned research priorities, but it was often mediated by ideological or administrative imperatives. After 1989, the restoration of autonomy and the reorientation towards international disciplinary standards were necessary and legitimate. Yet the post-socialist recovery of disciplines also risked reinforcing separation between research communities. Strategy AV21 belonged to a later phase, in which the Academy could move beyond the defensive reconstruction of disciplines towards more confident cooperation among them. This was possible precisely because the Academy had already stabilised itself institutionally and scientifically after the transformation period.

The crossing of boundaries also changed the meaning of leadership inside the Academy. Traditional leadership in a research institute is usually connected with disciplinary authority, institute management, project acquisition, and publication quality. Strategy AV21 added another type of leadership: the capacity to coordinate across institutes, communicate across disciplines, and formulate a problem in a way that different research cultures can recognise. Programme coordinators therefore occupied a strategic position. They were not simply administrators, nor were they only senior scholars in their own fields. They had to translate between scientific languages, institutional interests, external partners, Academy leadership, and public communication. In this respect, Strategy AV21 encouraged a more networked form of academic leadership.

The boundary-crossing logic was visible from the early programme titles. Themes such as "Hopes and Risks of the Digital Age", "Natural Hazards", "Foods for the Future", "Quality of Life and Health", "Effective Public Policies and Contemporary Society", "Memory in the Digital Age", and "Forms and Functions of Communication" already implied more than one discipline. Each title named not a discipline but a field of problems. Such naming was important because it invited institutes to enter the programme through different competences. It also made the programmes more understandable to audiences outside the Academy. A citizen, policymaker, entrepreneur, or journalist may not know the internal map of Academy institutes, but they can understand why food, health, energy, communication, memory, or digital risks matter.

The same principle can be seen in later developments of the strategy. As new programmes appeared, the Academy continued to organise cooperation around public-interest themes rather than around disciplinary labels. Programmes connected with artificial intelligence, biodiversity, infectious diseases, identity, materiality, and sustainable energy all presupposed participation by multiple institutes and partner organisations. This evolution showed that interdisciplinarity was not a one-time decorative feature of the 2015 launch. It became part of

the Academy's continuing strategic grammar. The Academy learned to present its research through problems that demanded coordination across the institutional map (*Czech Academy of Sciences, 2026*).

Crossing boundaries between institutes also strengthened the Academy's ability to cooperate with universities. Universities possess their own disciplinary structures, faculties, doctoral programmes, and research centres. The Academy's programme framework made it easier to connect with them around shared themes rather than isolated bilateral contacts. A university partner could join a programme because it worked on energy, public policy, artificial intelligence, memory, biodiversity, or health, even if the relevant Academy expertise was distributed across several institutes. This improved the visibility and practicality of collaboration. Strategy AV21 therefore did not only reorganise the Academy internally; it created clearer channels for cooperation with the broader Czech research system.

The same applied to relations with state and regional administration. Public authorities often need knowledge organised around policy problems, not around disciplinary divisions. A ministry concerned with energy, health, environment, education, culture, security, or innovation needs integrated expertise. It may not know which institute or discipline should be approached first. Strategy AV21 made the Academy's expertise more accessible by grouping relevant capacities into programmes. This did not turn the Academy into an administrative consultancy. Rather, it allowed public authorities to recognise where long-term research knowledge could inform decision-making. The programme format thus made academic expertise more legible to government without subordinating it to government.

Business and industrial partners also benefited from this boundary-crossing structure. Industrial innovation often requires materials science, chemistry, engineering, modelling, biotechnology, optics, data analysis, environmental assessment, and regulatory understanding. A single institute may offer a strong competence, but complex innovation frequently depends on several competences assembled together. Strategy AV21 created a more coherent interface between the Academy and the application sphere. It helped identify research areas where cooperation could produce economic and social benefit while remaining anchored in scientific quality. This was consistent with the Academy's attempt to become an important knowledge actor in the national innovation system without losing its academic identity.

The humanities and social sciences played a crucial role in preventing interdisciplinarity from becoming merely technical integration. Without them, Strategy AV21 might have become a programme of laboratories cooperating with industry, useful but intellectually narrower than the Academy's mission required. The inclusion of memory, communication, public policy, European statehood, global conflicts, identity, and cultural heritage showed that the Academy understood public-interest problems as human and social problems as well as technological ones. Historical interpretation, linguistic analysis, philosophical reflection, economic modelling, sociological research, legal expertise, and political analysis all helped broaden the meaning of interdisciplinary research. This was essential for an institution whose legitimacy had always included the cultural and intellectual life of the nation.

The crossing of boundaries also had epistemological consequences. Different disciplines do not merely study different objects; they construct evidence differently. Experimental sciences often privilege reproducibility, measurement, and controlled intervention. Historical sciences privilege contextual reconstruction, source criticism, and temporal explanation. Social

sciences combine empirical data, theory, interpretation, modelling, and institutional analysis. Mathematical and computational sciences work through abstraction, formalisation, and simulation. Strategy AV21 required these epistemic cultures to interact. Such interaction does not automatically produce agreement, but it can produce richer problem definitions. The public interest is often served not by one discipline winning over others, but by a more complete understanding of the problem.

This epistemological pluralism was particularly important in areas such as artificial intelligence. AI can be studied as mathematics, software, data infrastructure, industrial technology, cognitive model, ethical problem, legal challenge, labour-market force, educational tool, and cultural phenomenon. No single discipline can claim full authority over it. Strategy AV21's interdisciplinary orientation made it possible to frame AI as both a scientific instrument and a social object. This framing is more adequate than either technological enthusiasm or cultural alarmism alone. It shows how the Academy can use its internal diversity to produce a balanced understanding of emerging technologies.

The same is true of environmental sustainability. A forest affected by climate change is at once a biological system, an economic resource, a cultural landscape, a legal object, a recreational space, and a political issue. Water scarcity is a hydrological phenomenon, but also a matter of agriculture, infrastructure, governance, behaviour, and regional inequality. Biodiversity loss is an ecological process, but it also affects food systems, land use, public perception, and ethical responsibility towards future generations. Strategy AV21's boundary-crossing format allowed the Academy to treat such issues with the necessary breadth. It made environmental knowledge less isolated and more socially connected.

Health research provides another clear example. Modern health challenges cannot be solved by biomedical laboratories alone, although laboratory research is indispensable. Ageing populations, chronic disease, epidemics, mental health, diagnostics, therapeutics, nutrition, and health inequalities all require interaction between biology, medicine, chemistry, data science, demography, psychology, sociology, ethics, and public communication. Strategy AV21 created a framework in which these different areas could appear as parts of one public-interest field. The Academy's strength lay in its ability to connect molecular and social levels of analysis. This connection became especially visible during and after the COVID-19 pandemic, when the relationship between science, public trust, communication, and policy became unavoidable.

The strategy also helped connect small or highly specialised research communities to larger public narratives. Some fields within the Academy are intellectually sophisticated but not immediately visible to the public. Advanced spectroscopy, protein chemistry, medieval textual scholarship, formal logic, plant physiology, seismology, or computational image processing may not easily attract broad attention by themselves. When placed within programmes on health, heritage, digitalisation, natural hazards, materials, or sustainability, however, their public relevance becomes clearer. Strategy AV21 therefore did not simply favour fashionable topics. It helped demonstrate how specialised knowledge contributes to larger challenges.

This also affected the internal morale of the Academy. Researchers working in specialised fields could see their work recognised within broader institutional missions without being forced to abandon their research identity. Such recognition matters because public debate often values only immediately visible scientific achievements. Strategy AV21 allowed less visible forms of expertise to be connected with public interest through programme narratives.

It made the Academy's internal diversity more intelligible both to society and to the researchers themselves. In this sense, interdisciplinarity was not only a governance principle, but also a form of institutional self-recognition.

The crossing of boundaries between institutes required practical mechanisms. It required meetings, programme councils, shared workshops, joint publications, public events, common communication platforms, grant cooperation, coordination with the Academy Council, and reporting procedures. It also required financial support sufficient to make collaboration more than a voluntary burden added to normal research duties. Interdisciplinarity becomes real only when institutions create time, incentives, recognition, and administrative channels for it. Strategy AV21 therefore had to translate an intellectual ideal into working routines. Its success depended on whether researchers experienced programmes as meaningful opportunities rather than bureaucratic additions.

At the same time, interdisciplinary programmes risk becoming too broad if their boundaries are not defined carefully. A programme on "society", "technology", or "environment" can easily expand until it includes almost everything. Strategy AV21 had to avoid this danger by formulating programmes around recognisable but researchable themes. The best programmes are broad enough to invite multiple disciplines, but focused enough to generate cooperation, outputs, and public meaning. This balance is difficult, and it must be continually renegotiated. The Academy's experience with Strategy AV21 can therefore be read as an experiment in managing breadth without losing intellectual precision.

Another challenge concerned evaluation. Disciplinary research can often be assessed through established peer-review communities, journals, citation patterns, and professional standards. Interdisciplinary research is harder to evaluate because it may produce diverse outputs, address mixed audiences, and combine methods that no single discipline can fully judge. Strategy AV21 therefore required evaluation practices sensitive to both scientific quality and public relevance. This did not mean lowering standards. It meant recognising that a programme's value might include publications, technologies, policy contributions, public communication, methodological innovation, data infrastructures, cultural outputs, and new collaborative networks. The Academy's strategic format thus pushed evaluation beyond narrow disciplinary metrics.

The programme structure also helped the Academy respond to the problem of scale. Some research questions are too large for one institute but too specific to become a national ministry programme. Strategy AV21 created an intermediate scale: larger than an individual grant, smaller and more flexible than a state strategy, and more scientifically grounded than a policy slogan. This intermediate scale suited the Academy's position in the Czech research system. It enabled AV ČR to mobilise several institutes and partners around a theme while retaining academic control over research content. Such a scale is one of the distinctive organisational contributions of Strategy AV21.

The crossing of boundaries was also communicative. Programmes gave the Academy stories that could be told publicly. Instead of listing institutes and their achievements separately, the Academy could explain how researchers from different fields worked together on energy, health, memory, AI, biodiversity, or materials. This narrative form mattered because public communication is not only the transmission of facts. It is also the construction of understandable connections. Strategy AV21 made those connections visible. It allowed the

public to see the Academy as a coordinated intellectual actor rather than as a remote collection of expert enclaves.

The boundary-crossing principle also connected the Academy's domestic role with its international position. International research increasingly operates through consortia, networks, infrastructures, joint projects, and interdisciplinary calls. Institutes that learn to cooperate internally are better prepared to participate externally. Strategy AV21 therefore strengthened the Academy's capacity for European and global collaboration. It helped researchers move from local institute-based work to broader thematic networks. This was especially important in areas aligned with European priorities, such as climate, health, digital transformation, security, food systems, and cultural heritage.

In this sense, Strategy AV21 can be understood as an institutional rehearsal for the wider research world of the 21st century. The Academy's internal borders became training grounds for crossing external borders as well. Researchers who learned to collaborate across institutes could more easily cooperate with universities, ministries, companies, regions, international consortia, and civil society. The strategy therefore developed not only projects, but habits of cooperation. These habits may be among its most durable effects. They change how an academy thinks about its own internal map.

The intellectual importance of this change should not be underestimated. A classical academy often gains authority from depth, distance, and continuity. A public-interest research institution must retain those qualities while adding connection, responsiveness, and translation. Strategy AV21 did not abolish the classical academy; it opened it. It encouraged institutes to see themselves not only as guardians of disciplinary excellence, but as participants in shared problem-solving. This was a significant cultural shift, because it changed the relationship between institutional identity and public responsibility.

Thus, crossing boundaries between institutes and disciplines became one of the defining organisational principles of Strategy AV21 because it allowed the Czech Academy of Sciences to convert its internal plurality into strategic capacity. The Academy did not abandon specialised institutes, disciplinary standards, or long-term research cultures. Instead, it created programme-based mechanisms through which these strengths could interact around complex public-interest challenges. This made the Academy more visible, more cooperative, more responsive, and more capable of speaking to society without sacrificing scholarly depth. Strategy AV21 therefore turned interdisciplinarity from an abstract ideal into an institutional practice: a way of connecting laboratories, archives, field research, computation, social analysis, humanities, policy expertise, and external partners within one national knowledge institution.

2. Programme-Based Research and Collaborative Governance

Programme-based research became one of the most important organisational innovations of Strategy AV21 because it gave the Czech Academy of Sciences a form of coordination suited to complex public-interest problems. The Academy did not abandon its institute structure, nor did it create a new centralised hierarchy above the institutes. Instead, it introduced research programmes as flexible but recognisable frameworks through which several institutes, disciplines, and external partners could work on shared themes. This was a significant shift in institutional logic. The basic unit of scientific life remained the institute, but the basic unit of

strategic public presentation became the programme. Strategy AV21 therefore created an additional layer of organisation: not a replacement for institutes, but a connective architecture that made their cooperation more visible, purposeful, and accountable. In this sense, programme-based research was both a managerial tool and a cultural change in how the Academy understood its collective mission (*Czech Academy of Sciences, 2017*).

The programme format was necessary because contemporary challenges rarely correspond to the boundaries of a single institute. An institute may possess deep competence in a specialised field, but public problems often require a combination of competences distributed across the Academy. Energy transition may require physics, materials science, environmental modelling, economic analysis, and risk communication. Public health may require molecular biology, epidemiology, chemistry, demography, sociology, and public policy. Artificial intelligence may involve mathematics, computer science, linguistics, ethics, law, psychology, and industrial application. Cultural memory may involve history, archaeology, philology, literary studies, digital humanities, media studies, and education. Programme-based research allowed the Academy to assemble these capacities around problems rather than around institutional borders.

This is why Strategy AV21 should not be interpreted as a simple catalogue of projects. A project is usually time-limited, competitively funded, and defined around a more specific research objective. A programme, by contrast, is broader, more synthetic, and more strategic. It can contain several projects, working groups, partnerships, public events, policy outputs, publications, technologies, and communication activities. It provides a thematic roof under which diverse research activities can be connected without being forced into artificial uniformity. Strategy AV21 used the programme format precisely because the Academy needed a scale larger than the individual grant but more flexible than a state research plan. It offered an intermediate organisational form appropriate to a national academy of specialised institutes.

The programme-based model also helped the Academy move from reactive expertise to proactive agenda formation. In a reactive model, public institutions come to researchers when a problem has already become urgent, politically visible, or administratively defined. In the Strategy AV21 model, the Academy itself identified areas where its knowledge could matter for the future of society. This did not mean that the Academy claimed exclusive authority over social priorities. Rather, it meant that scientists took responsibility for formulating research agendas before public debate reduced complex problems to slogans. Programme-based research therefore allowed the Academy to act not only as a supplier of expertise, but also as a strategic interpreter of emerging challenges. This was a more ambitious public role.

Collaborative governance was the necessary counterpart of this programme logic. Once research is organised across institutes, disciplines, and partner organisations, it cannot be governed only through the normal vertical channels of institute management. It needs coordination, negotiation, shared priorities, evaluation, communication, and mechanisms for resolving tension between different research cultures. Strategy AV21 therefore required forms of governance that were neither purely hierarchical nor purely informal. Programmes had coordinators, participating institutes, thematic objectives, reporting obligations, and links to the Academy's central bodies. At the same time, they depended on voluntary intellectual cooperation and the willingness of researchers to work beyond their usual institutional

environments. This combination of structure and flexibility was central to the strategy's functioning.

The figure of the programme coordinator became especially important. A coordinator had to do more than administer a budget or collect reports. The role required scientific credibility, organisational skill, diplomatic sensitivity, and the ability to translate between disciplines and institutions. Coordinators had to recognise which institutes could contribute, how different research strands could be connected, and how a programme could speak to public audiences without oversimplifying its scientific content. They also had to maintain relations with external partners, including universities, public authorities, companies, cultural institutions, and foreign research groups. In this respect, Strategy AV21 created a new form of academic leadership: leadership by connection rather than only leadership by disciplinary seniority.

This collaborative leadership differed from the older image of the academy as a community of relatively self-contained scholarly authorities. In a classical model, academic prestige often comes from individual achievement, school formation, or institutional position. Under Strategy AV21, prestige also depended on the capacity to mobilise knowledge across boundaries. A successful programme required someone to build a network, maintain trust, articulate common goals, and produce outcomes that made sense to several audiences. This did not diminish individual scholarship, but it placed individual scholarship within larger cooperative structures. The Academy thereby adjusted its internal culture to a research world where collaboration, interdisciplinarity, and public relevance had become unavoidable.

The governance of Strategy AV21 also had to respect the autonomy of participating institutes. This was crucial because the Academy's strength rests on institutes with their own scientific identities and long-term priorities. If programmes had been imposed too rigidly from above, they might have been perceived as administrative burdens or as threats to institute autonomy. If they had been left entirely to spontaneous cooperation, however, they might have lacked strategic coherence. The programme-based model therefore had to balance autonomy and coordination. It encouraged institutes to participate in common programmes while preserving their disciplinary missions, internal leadership, and research independence. This balance was one of the most delicate institutional achievements of Strategy AV21.

The model also helped the Academy respond to the limitations of competitive grant funding. Competitive grants are essential for scientific dynamism, but they can fragment research into short-term cycles and encourage teams to pursue fundable topics rather than long-term strategic problems. Programme-based research offered a complementary logic. It allowed the Academy to maintain attention to broad themes over several years and to connect individual projects within a wider intellectual frame. This did not remove competition from the research environment, but it softened some of its fragmenting effects. Strategy AV21 therefore served as an instrument of continuity in a system increasingly shaped by project-based funding.

At the same time, the programme format was compatible with external funding and international cooperation. A well-defined strategic programme could help researchers identify grant opportunities, build consortia, attract partners, and present Czech expertise within European research agendas. Programmes on energy, health, artificial intelligence, biodiversity, materials, or cultural heritage could align with European priorities while retaining their own Academy-based intellectual structure. This made Strategy AV21 useful not only for domestic coordination, but also for positioning AV ČR in the European Research Area.

Programme-based governance thus operated at several levels: inside the Academy, within the Czech research system, and across international networks.

The relationship between programme-based research and collaborative governance can also be seen in the strategy's openness to external actors. Strategy AV21 was not designed as a closed internal initiative of Academy institutes alone. It encouraged cooperation with universities, public administration, regions, business, foreign research groups, and other organisations. This openness followed logically from the public-interest mission. If research is meant to address social, technological, environmental, cultural, and economic challenges, it must communicate with the institutions and communities affected by those challenges. Collaborative governance therefore extended beyond the Academy's walls. It created channels through which scientific knowledge could meet policy, practice, industry, education, culture, and public debate.

Such openness, however, required careful protection of scientific independence. Collaboration with ministries, companies, regions, or public organisations can be productive, but it can also create pressure to adapt research questions to external expectations. Strategy AV21 had to avoid the danger of turning the Academy into a consultancy service. Its programmes were public-interest programmes, not client-driven assignments. The Academy could cooperate with external partners while retaining control over scientific standards, methods, and interpretation. Collaborative governance therefore had to be based on partnership rather than subordination. This distinction was essential for preserving the Academy's identity as an autonomous research institution.

The programme format also allowed the Academy to handle different kinds of outputs. Traditional academic governance often privileges journal articles, monographs, conference papers, and disciplinary evaluation. Strategy AV21 could include these outputs, but it also had to recognise policy briefs, public lectures, educational materials, exhibitions, technologies, prototypes, databases, software, patents, expert opinions, media communication, and cooperation platforms. This broader output structure reflected the public-interest orientation of the strategy. It did not mean that scholarly quality became less important. It meant that the Academy acknowledged several pathways through which research can create public value. Programme-based governance had to make these pathways visible and credible.

This broader understanding of outputs was especially important for the social sciences and humanities. Their contributions to public interest often take the form of interpretation, critical analysis, historical contextualisation, conceptual clarification, public debate, or policy evaluation. These contributions may not always resemble technological innovation, but they can be crucial for democratic society. A programme on memory, communication, identity, public policy, or Europe cannot be evaluated only through the same indicators as a programme on materials or diagnostics. Strategy AV21 therefore required governance sensitive to disciplinary plurality. It had to combine common strategic aims with differentiated criteria of value.

The same principle applied to natural and technical sciences. In some fields, public value may appear through prototypes, patents, industrial cooperation, or medical applications. In others, it may appear through long-term data, modelling, monitoring, risk assessment, or expert infrastructure. Environmental research, for example, often produces value through continuity, observation, and early warning rather than through immediate commercial outputs. Physics or chemistry may produce knowledge whose practical significance emerges only later.

Programme-based governance had to recognise these temporal differences. Public-interest research cannot be governed as if all useful knowledge matures at the same speed.

The collaborative character of Strategy AV21 also changed the relationship between research and communication. Communication was not simply an activity added after scientific work had been completed. In many programmes, public communication formed part of the programme's social function. Research on digital risks, public health, climate change, energy systems, biodiversity, or cultural memory requires explanation, translation, and dialogue with society. Programme governance therefore had to include communication planning, not only scientific planning. This helped the Academy move from the older model of expert knowledge hidden inside institutes towards a more visible and dialogic public presence. Such visibility was central to the modern image of AV ČR.

Nevertheless, collaborative governance is never simple. It can generate conflicts over priorities, authorship, resources, visibility, intellectual ownership, and the division of labour between institutes. A programme that brings together several disciplines may reveal genuine disagreements about methods or problem definitions. External partners may expect faster or more practical outcomes than researchers can responsibly provide. Public communication may favour attractive narratives over methodological complexity. Strategy AV21 had to manage these tensions rather than pretend they did not exist. Its institutional maturity depended on creating coordination mechanisms capable of sustaining cooperation through disagreement.

The programme-based model also required trust. Formal rules can establish structures, but collaboration depends on whether researchers believe that participation is worthwhile. They must see programmes as intellectually productive, not merely as another layer of reporting. They must trust coordinators, partner institutes, and central Academy bodies. They must believe that their disciplinary contributions will be recognised fairly within broader programmes. Strategy AV21 therefore relied on an internal culture of cooperation built gradually through repeated interaction. Such culture cannot be produced instantly by strategic documents. It develops through practice, successful examples, and the demonstration that collaboration can strengthen rather than dilute research.

The long-term character of Strategy AV21 was important in this regard. Programmes operating over several years allowed relationships to mature. Researchers could learn how other disciplines work, discover complementary competences, and develop shared vocabularies. Short-term calls often do not provide enough time for such learning. A five-year programme horizon created better conditions for interdisciplinary trust and cumulative cooperation. It also allowed programmes to adjust their activities according to new findings, external events, and changing social needs. This flexibility was a practical expression of collaborative governance.

Programme-based research also gave the Academy a way to integrate basic and applied research without forcing a simplistic division between them. Within a single programme, some teams might work on fundamental mechanisms, others on technological development, others on social implications, and others on communication or policy relevance. The programme did not have to classify the whole field as either basic or applied. It could contain a chain of knowledge production from theoretical inquiry to public use. This was one of the strengths of Strategy AV21 because it reflected how science often works in reality. Fundamental research and application are not always separate stages; they frequently interact inside broader problem fields.

The strategy's governance also interacted with the Academy's evaluation culture. After the post-socialist reforms, AV ČR increasingly relied on evaluation to maintain quality and international credibility. Strategy AV21 added another dimension: the need to assess not only individual institutes or disciplinary outputs, but also collaborative programmes. This raised difficult questions. How should one evaluate a programme whose value lies in networks, preparedness, public communication, and long-term capacity-building? How should one compare a programme producing prototypes with one producing policy evidence or historical interpretation? These questions do not have simple answers, but the programme format made them unavoidable. It pushed the Academy towards a more nuanced understanding of performance.

Collaborative governance also strengthened the Academy's ability to speak with a more unified voice. A decentralised academy can produce excellent research while remaining publicly difficult to understand. Programme-based structures gave AV ČR thematic platforms through which it could present its work coherently. Instead of communicating only institute by institute, the Academy could speak about energy, health, AI, biodiversity, memory, materials, public policy, or communication. This did not eliminate the diversity of institutes, but it gave that diversity a strategic narrative. Such narrative unity is especially important when an institution must justify public funding and demonstrate national relevance.

The programme model also affected relations between senior and early-career researchers. Large collaborative programmes can create opportunities for younger scholars to participate in networks beyond their home institute, gain visibility, develop interdisciplinary competences, and work with external partners. At the same time, they can also reproduce hierarchies if coordination remains concentrated among established figures. The democratic potential of programme-based research therefore depends on how programmes organise participation. Strategy AV21's long-term significance should be judged partly by whether it helps create a new generation of researchers comfortable with both disciplinary excellence and collaborative responsibility.

Another important feature of programme-based governance was its capacity to respond to new themes. The development of new programmes in areas such as artificial intelligence, biodiversity, infectious diseases, materiality, identity, and other emerging topics showed that Strategy AV21 was not frozen in its original form. It could be renewed as scientific and social priorities changed. This adaptability distinguished the strategy from a rigid institutional plan. It allowed the Academy to keep the motto "Top research in the public interest" stable while revising the thematic content through which that motto was realised. Programme-based research thus gave the Academy both continuity and responsiveness (*Czech Academy of Sciences, 2026*).

The presence of external partners also linked Strategy AV21 with broader theories of collaborative governance. In public administration literature, collaborative governance describes arrangements in which public agencies, private actors, experts, and civil society organisations participate in structured decision-making or problem-solving processes (*Ansell & Gash, 2008*). Strategy AV21 was not collaborative governance in exactly the same sense as a policy-making forum, because the Academy remained a research institution rather than a governing authority. Yet the concept is useful because it highlights the importance of trust, shared goals, facilitation, institutional design, and iterative cooperation. The Academy's

programmes operated in this space between research coordination and public problem-solving. They were scientific programmes, but their governance had public-facing features.

Programme-based research also reflected the growing importance of networks in modern science. Scientific discovery and innovation increasingly depend on distributed expertise, shared infrastructures, international consortia, data platforms, and cross-sectoral cooperation. No single institution, however strong, can cover all dimensions of a major challenge alone. Strategy AV21 acknowledged this reality by treating the Academy as a node in wider knowledge networks, while still preserving its role as a national anchor of expertise. This dual position was important. AV ČR could cooperate widely because it had strong internal capacities; it could maintain national strategic relevance because it was open to external knowledge flows.

The governance of Strategy AV21 therefore had a constitutional meaning for the Academy's modern identity. It showed how AV ČR could remain an academy of institutes while also acting as an integrated public-interest research institution. This identity required more than excellent publications. It required institutional mechanisms for assembling expertise, defining programmes, communicating results, engaging partners, and adjusting priorities. Strategy AV21 provided these mechanisms in a form compatible with the Academy's history and autonomy. It did not impose a ministry-style planning model, nor did it leave cooperation to chance. It created a strategic middle layer through which the Academy could act collectively.

This middle layer was particularly valuable because the Academy's institutional history had made it cautious about centralised control. The experience of the socialist period had shown how dangerous political direction of science could be. The post-1989 transformation therefore placed strong emphasis on autonomy, evaluation, and international standards. Strategy AV21 had to build coordination without reviving the memory of ideological planning. Its programme-based governance was successful precisely because it framed coordination as scientific cooperation in the public interest, not as command. The Academy could therefore coordinate more strongly while remaining faithful to the post-1989 principle of intellectual freedom.

The distinction between coordination and control is central here. Coordination helps researchers connect, share resources, define common questions, and communicate public value. Control dictates what researchers must conclude or how they must serve external power. Strategy AV21 belonged to the first category. It gave direction without prescribing results. It identified themes without closing inquiry. It promoted public relevance without reducing science to political obedience. This distinction allowed the Academy to recover the positive meaning of strategy after a 20th-century history in which strategic planning had often been associated with ideological constraint.

Programme-based governance also helped the Academy cope with the complexity of public-interest language. Public interest is not self-evident. Different actors may define it differently: ministries, municipalities, companies, citizens, scientists, patients, teachers, cultural institutions, and future generations may all have different expectations. Programmes provided spaces where these expectations could be interpreted through research rather than accepted uncritically. The Academy's role was not simply to follow external demand, but to transform social concerns into scientifically meaningful questions. This transformation required collaborative governance because no single researcher or institute could define the public interest alone.

At the same time, programme-based research gave the Academy a better basis for accountability. A strategic programme has a name, coordinator, participating bodies, objectives, outputs, and public visibility. It can be discussed, reviewed, modified, and communicated. This is different from a diffuse claim that the Academy as a whole serves society in some general way. Strategy AV21 made public-interest activity more concrete. It allowed the Academy to show where resources were directed, which problems were being addressed, and how different institutes contributed. Accountability was therefore strengthened not through bureaucratic centralisation, but through thematic transparency.

The collaborative governance of Strategy AV21 also affected the symbolic image of the Academy. It presented AV ČR not as a closed corporation of scholars, but as an institution capable of organising knowledge for society. This image mattered in a democratic environment where public institutions must continually explain their relevance. The Academy could show that it was open to cooperation, responsive to contemporary problems, and willing to communicate beyond specialist circles. At the same time, it could show that such openness rested on serious research and long-term expertise. The programme format therefore became a bridge between scientific authority and public legitimacy.

Thus, programme-based research and collaborative governance formed the organisational core of Strategy AV21 because they allowed the Czech Academy of Sciences to coordinate its dispersed capacities without abandoning institute autonomy. The programme model created a strategic layer between individual research projects and the Academy as a whole. It enabled interdisciplinary cooperation, external partnership, broader communication, and more flexible responses to emerging challenges. Collaborative governance made this model workable by relying on coordinators, negotiated priorities, trust, reporting, public visibility, and respect for disciplinary diversity. In this way, Strategy AV21 transformed the Academy from a collection of excellent institutes into a more integrated public-interest research institution. It did so not by centralising science, but by creating a programme architecture through which autonomy, excellence, cooperation, and public responsibility could operate together.

3. The Integration of Natural, Technical, Social, and Human Sciences

The integration of natural, technical, social, and human sciences became one of the most distinctive features of Strategy AV21 because it expressed a mature understanding of what public-interest research requires in the 21st century. The Czech Academy of Sciences did not present contemporary challenges as problems that could be solved by one dominant type of knowledge. It recognised that energy, climate, health, security, digitalisation, biodiversity, public policy, cultural memory, and human identity all have several layers at once. They are physical and biological, but also technological, social, political, economic, historical, ethical, and cultural. Strategy AV21 therefore moved beyond the older hierarchy in which “hard” sciences were treated as the main producers of useful knowledge and the humanities as guardians of cultural memory alone. It created a research architecture in which different scientific cultures could contribute to shared public questions. This was not a decorative pluralism. It was a practical necessity arising from the structure of modern problems themselves (*Czech Academy of Sciences, 2017*).

The natural sciences brought to Strategy AV21 the capacity to investigate the material, biological, ecological, chemical, physical, and planetary conditions of human life. Climate

change, ecosystem transformation, infectious diseases, ageing, food systems, energy conversion, water management, and biodiversity all require empirical research into processes that cannot be understood through social interpretation alone. The Academy's institutes in biology, chemistry, physics, earth sciences, mathematics, and environmental research provided long-term expertise, instruments, data, fieldwork, modelling, and experimental methods. This gave the strategy scientific depth and credibility. Yet the natural sciences could not by themselves define the full meaning of public interest. Their findings had to be connected with questions of governance, behaviour, regulation, communication, values, and historical context. Strategy AV21 therefore placed natural science at the centre of public-interest research, but not in isolation from the rest of knowledge.

The technical sciences and engineering-oriented fields added another indispensable dimension. They transformed scientific understanding into instruments, materials, technologies, diagnostics, energy systems, sensors, digital tools, industrial processes, and practical infrastructures. In the Academy's modern profile, technical research did not stand outside basic science; it often grew directly from fundamental discoveries in physics, chemistry, materials science, computation, optics, plasma research, and biotechnology. Strategy AV21 gave these fields a strategic frame by linking them with national needs in energy, industry, health, environmental adaptation, digitalisation, and security. Technical research thus became one of the bridges between the Academy and the application sphere. However, Strategy AV21 avoided reducing technical work to commercialisation alone. Its technological orientation remained embedded in a broader public-interest mission, where innovation was evaluated not only by market value, but also by social usefulness, safety, sustainability, and long-term resilience (*Etzkowitz & Leydesdorff, 2000*; *Czech Academy of Sciences, 2026*).

The social sciences entered this architecture by asking how societies organise, distribute, accept, resist, regulate, and interpret change. A technological solution may fail if institutions are weak, citizens distrust it, inequalities deepen, or policy design is poor. A public health recommendation may be scientifically valid and still ineffective if communication, social behaviour, legal frameworks, and public trust are neglected. Climate adaptation depends not only on models and measurements, but also on agriculture, municipalities, household behaviour, investment priorities, land ownership, and political decision-making. Strategy AV21 therefore needed economics, sociology, political science, law, psychology, demography, geography, public administration, and communication studies. These fields made visible the social conditions under which scientific knowledge becomes public action. They also protected the Academy from the technocratic illusion that society can be redesigned by expertise alone.

The humanities contributed another layer that was equally essential, although less easily measured by conventional innovation indicators. History, philosophy, philology, literary studies, archaeology, art history, ethnology, linguistics, and cultural studies help societies understand memory, identity, language, meaning, tradition, conflict, and moral orientation. Contemporary challenges are never only material or institutional; they are also interpretative. Societies respond to crises through narratives, symbols, memories, fears, hopes, and inherited cultural categories. Strategy AV21's inclusion of memory, communication, Europe, statehood, identity, materiality, and cultural heritage showed that the Academy understood this. The humanities did not merely decorate the strategy with cultural legitimacy. They helped define the human meaning of public-interest research.

This integration was particularly important because the Czech Academy of Sciences has historically carried a broader intellectual mission than many specialised research organisations. From the learned societies of the Czech lands to the modern Academy, scientific institutions were repeatedly connected with language, national culture, education, historical consciousness, and public life. During the national revival, scholarship was part of cultural self-definition. Under socialism, the public mission of science was distorted by ideological control. After 1989, the Academy reclaimed autonomy and international standards. Strategy AV21 represented a further stage: it reconnected science with society, but in a democratic and interdisciplinary form. The integration of natural, technical, social, and human sciences therefore continued a long tradition while giving it a new institutional language.

The programme-based structure of Strategy AV21 made this integration operational. Rather than organising research under disciplinary headings, programmes were formulated around problems: energy, health, food, natural hazards, digital risks, materials, communication, public policy, memory, biodiversity, infectious diseases, artificial intelligence, identity, and other complex themes. Such themes naturally invited several fields to participate. A programme on artificial intelligence could include algorithmic research, data science, language technologies, ethics, law, education, psychology, labour studies, and public communication. A programme on biodiversity could include ecology, botany, zoology, genetics, landscape studies, climate science, economics, law, and environmental policy. A programme on memory could include history, archival research, digital technologies, sociology, media studies, philosophy, education, and cultural analysis. The title of the programme thus became a meeting point for different sciences.

The integration of scientific areas also changed the way public problems were defined. A narrowly technical definition often presents a problem as a lack of tools. A narrowly social definition may present it as a failure of institutions or behaviour. A narrowly cultural definition may present it as a crisis of meaning or identity. Strategy AV21 encouraged a more layered understanding. Energy transition, for example, becomes at once a question of physical systems, engineering capacities, environmental limits, economic costs, public trust, geopolitical vulnerability, and future social choices. Public health becomes a matter of molecular mechanisms, diagnostics, clinical translation, demographics, communication, inequality, law, and ethics. Cultural memory becomes a matter of archives and interpretation, but also of digital infrastructures, education, political legitimacy, and social cohesion. This layered definition is one of the main intellectual achievements of the strategy.

The Academy's natural and technical sciences gained from this integration because their public relevance became more visible. Research in plasma physics, advanced materials, molecular biology, atmospheric physics, plant science, or computational modelling can be difficult for the public to grasp when presented in isolation. When placed within programmes on energy, health, sustainability, food, artificial intelligence, or future industries, its meaning becomes clearer. This does not simplify the science itself, but it clarifies why it matters. Strategy AV21 thus helped specialised research communities articulate their public significance without abandoning disciplinary depth. It gave them a language through which fundamental work could be connected to long-term social challenges.

The social sciences and humanities also gained from the integrative format because they were placed at the centre of contemporary problem-solving rather than at the margins of cultural commentary. A programme on public policy, communication, identity, memory, or society in

motion does not merely accompany technological change; it analyses the conditions under which change becomes socially meaningful or dangerous. The humanities and social sciences help explain why evidence is accepted or rejected, why reforms succeed or fail, why societies remember selectively, and why technological futures are imagined in conflicting ways. Strategy AV21 therefore made these fields strategically necessary. It showed that public-interest research requires not only instruments and data, but also interpretation, judgement, and institutional understanding.

This integration also helped overcome the outdated opposition between "useful" and "non-useful" sciences. In narrow policy language, usefulness is often associated with technologies, patents, industrial cooperation, or measurable economic impact. Strategy AV21 broadened this meaning. A mathematical model can be useful, but so can a historical analysis of collective memory. A new material can be useful, but so can research into public trust during crises. A biomedical method can be useful, but so can linguistic research into communication and misinformation. The public interest is not exhausted by market application. It includes resilience, democratic understanding, cultural continuity, social diagnosis, environmental responsibility, and the ability of citizens to orient themselves in complex realities (*Bozeman, 2007*).

The integrative logic also made Strategy AV21 compatible with European and international research trends. European research policy increasingly emphasised grand challenges, missions, responsible research and innovation, and cross-sectoral cooperation. Such frameworks assume that climate, health, digitalisation, food, security, and culture cannot be addressed by one discipline alone. The Academy's strategy therefore aligned Czech research with a broader European movement while preserving its own institutional identity. It was not merely following external policy terminology. It translated European challenge-oriented language into the specific structure of AV ČR, with its strong institutes, historical depth, and full disciplinary spectrum (*European Commission, 2021*; *Owen, Macnaghten, & Stilgoe, 2012*).

However, integration did not mean fusion into a single undifferentiated science. Strategy AV21 depended on the continued strength of individual disciplines. The Academy could integrate fields precisely because it had laboratories, archives, observatories, textual scholarship, field research, computational centres, collections, and disciplinary schools with their own methods. Without such depth, interdisciplinarity would become shallow rhetoric. The strategy therefore did not ask historians to become physicists, biologists to become sociologists, or engineers to become philosophers. It asked them to recognise where their knowledge met the knowledge of others in relation to a shared problem. This is a more demanding and more realistic understanding of interdisciplinarity than the simple celebration of mixed teams.

The integration of different sciences also required translation between epistemic cultures. Natural scientists often work with measurement, experiment, modelling, and causal mechanisms. Technical researchers focus on design, optimisation, functionality, and application. Social scientists analyse institutions, behaviour, data, norms, incentives, and social structures. Humanists interpret texts, artefacts, meanings, memories, values, and historical contexts. These cultures do not always ask the same questions or accept the same kinds of evidence. Strategy AV21 created spaces where such differences could be negotiated. The point was not to eliminate disagreement, but to make disagreement productive. A complex public problem is better understood when different epistemic cultures illuminate its different dimensions.

The integration of sciences was especially visible in environmental and sustainability programmes. Biodiversity loss, climate adaptation, landscape change, soil degradation, water scarcity, and ecosystem resilience are biological and physical processes, but they are also shaped by agriculture, law, economics, settlement, culture, and public perception. A purely ecological analysis may identify the problem, but implementation requires social and political understanding. Conversely, policy without ecological knowledge becomes empty administration. Strategy AV21 allowed the Academy to connect environmental research with social diagnosis and public communication. This made sustainability a scientific, institutional, and civic issue at the same time.

Health-related programmes showed the same pattern. Molecular biology, immunology, chemistry, pharmacology, physiology, and biomedical technologies form the scientific base of modern health research. Yet health outcomes are also influenced by age structure, inequality, lifestyle, communication, trust, healthcare organisation, and political decisions. The COVID-19 pandemic made this interdependence impossible to ignore. A virus is a biological entity, but a pandemic is also a social event. Strategy AV21's integrative logic was well suited to such a reality because it made room for biomedical research, data analysis, behavioural science, public communication, and policy interpretation within one broad public-interest horizon.

Artificial intelligence provides another strong example. AI is built on mathematics, computer science, statistics, data infrastructures, and engineering. But its social effects involve law, ethics, labour markets, education, media, language, security, psychology, creativity, and political power. A research institution that treats AI only as a technical problem risks misunderstanding its public significance. A society that treats AI only as a cultural fear risks missing its scientific and technological potential. Strategy AV21's integration of natural, technical, social, and human sciences allowed the Academy to frame AI as both a tool for research and a phenomenon transforming society. This dual framing is one of the reasons why the programme logic remained relevant as new technologies emerged.

The field of materials and future industries also demonstrates why integration was necessary. Advanced materials may begin in physics, chemistry, crystallography, nanoscience, or engineering, but their public value depends on industrial production, environmental impact, regulation, supply chains, safety, design, and economic strategy. A material suitable for energy storage, medicine, transport, or electronics must pass through several knowledge worlds before it becomes socially useful. Strategy AV21 made it possible to understand such fields as chains of knowledge rather than isolated discoveries. It also helped connect the Academy with Czech industry without reducing research to short-term industrial service.

Cultural heritage and memory programmes showed integration from the opposite direction. At first glance, memory may seem to belong primarily to the humanities. Yet in the digital age, memory also involves databases, digitisation, imaging technologies, information systems, preservation materials, computational analysis, media infrastructures, and public communication. Archaeology, art history, linguistics, history, and literary studies increasingly interact with chemistry, physics, computer science, and data management. Strategy AV21 therefore allowed heritage to be understood not as a static archive of the past, but as a technologically mediated, socially contested, and scientifically investigable field. This was an important modernisation of the Academy's cultural mission.

The integration of sciences also strengthened the Academy's role in public expertise. Policymakers and citizens rarely need disciplinary fragments alone. They need integrated

understanding: what is happening, why it matters, what risks exist, what options are available, what uncertainties remain, and what consequences may follow. Strategy AV21 helped the Academy assemble expertise in a form closer to these public needs. It did not turn scientists into politicians, but it allowed scientific knowledge to be presented in a more usable and responsible way. This is one of the reasons why Strategy AV21 became central to the Academy's modern public image.

At the same time, integration brought risks. Interdisciplinary programmes can become too broad, too vague, or too dependent on attractive public language. They can also privilege disciplines that produce visible outputs more quickly. Strategy AV21 had to guard against these dangers by maintaining scientific standards and clear programme objectives. Integration must not mean that disciplines are diluted into slogans. It must mean that strong disciplinary work is connected through serious intellectual coordination. The credibility of the strategy depended on this distinction.

Another risk concerned asymmetry between fields. Natural and technical sciences often command larger infrastructures, budgets, and public attention because their outputs can appear more concrete. Social sciences and humanities may be asked to provide communication, ethical reflection, or historical context after the main research agenda has already been defined. A genuinely integrative Strategy AV21 required something deeper. Social and human sciences had to participate in problem definition from the beginning, not merely comment on technical solutions after they were produced. The strongest version of Strategy AV21 was therefore not multidisciplinary addition, but interdisciplinary co-formation of research questions.

This co-formation was important for the Academy's democratic role. Public-interest research cannot be defined only by experts inside laboratories or by political actors outside them. It requires dialogue between knowledge, values, institutions, and citizens. Social sciences and humanities help reveal that public interest is not a self-evident technical category. It is historically formed, politically negotiated, legally structured, culturally interpreted, and ethically contested. Natural and technical sciences help ensure that public debate remains grounded in the realities of matter, life, energy, disease, data, and environmental systems. Strategy AV21's integrative logic brought these dimensions together.

The Academy's internal organisation made such integration both demanding and valuable. AV ČR includes institutes of very different size, discipline, history, and public visibility. Some work with large experimental devices, some with biological systems, some with mathematical abstraction, some with archives and texts, some with social data, and some with cultural artefacts. Strategy AV21 did not flatten this diversity. It used programme themes to make diversity productive. In this way, the Academy could become more than the sum of its institutes. It could act as a national knowledge institution whose strength lay precisely in the coexistence of different scientific worlds.

The integration of sciences also influenced public communication. A programme that combines biology, technology, sociology, and ethics can speak to society more fully than a narrowly disciplinary project. It can explain not only what researchers discovered, but why the discovery matters, what uncertainties remain, what decisions may follow, and how citizens are affected. This is particularly important in areas where public trust is fragile: vaccination, climate measures, nuclear energy, artificial intelligence, genetic technologies, migration, historical memory, and cultural identity. Strategy AV21 gave the Academy a structure through

which complex messages could be communicated without reducing them to simplistic slogans.

The integrative model also helped the Academy respond to crises. Crises expose the artificiality of disciplinary separation. A pandemic, flood, cyberattack, energy shock, war-related migration, or misinformation campaign immediately produces biological, technical, institutional, psychological, cultural, and political effects. An academy that has already cultivated interdisciplinary cooperation is better prepared to mobilise knowledge quickly and responsibly. Strategy AV21 therefore contributed to institutional resilience. It created habits of cooperation that could be activated when society needed integrated expertise.

This does not mean that Strategy AV21 solved all problems of interdisciplinary work. Integration remains slow, uneven, and dependent on people who can translate between fields. It requires administrative support, funding, recognition, and evaluation methods capable of appreciating diverse outputs. It also requires intellectual humility from researchers who must accept that their discipline sees only part of the problem. The value of Strategy AV21 lies not in perfect integration, but in making integration a normal and legitimate part of the Academy's work. It turned an aspiration into an institutional practice.

The integration of natural, technical, social, and human sciences also redefined the meaning of excellence. Excellence was no longer only the achievement of a field measured by its own internal standards. It also included the capacity to contribute to shared problems without losing scientific rigour. A researcher could remain excellent within a discipline and also become valuable as part of a broader programme. A programme could be excellent not because it replaced disciplinary science, but because it connected excellent disciplinary contributions in a way that produced new understanding. Strategy AV21 thus expanded, rather than weakened, the Academy's concept of high-quality research.

This expanded concept of excellence was essential for the Academy's public legitimacy. Society does not fund a national academy only to preserve separate disciplinary traditions, however valuable they may be. It also expects the Academy to help understand the world in which citizens live. Strategy AV21 showed that AV ČR could respond to this expectation by integrating its full intellectual spectrum. The Academy's public value lay in its ability to connect molecular processes with health, climate models with landscapes, digital systems with communication, materials with industry, policy analysis with social change, and memory with identity. Such connections made the Academy visible as a strategic institution rather than a collection of specialised workplaces.

Thus, the integration of natural, technical, social, and human sciences became a defining organisational and intellectual principle of Strategy AV21. It allowed the Czech Academy of Sciences to address contemporary challenges in their full complexity, without reducing them to technical tasks, social problems, or cultural questions alone. The strategy preserved disciplinary depth while creating programme-based spaces for cooperation across scientific cultures. It gave natural and technical sciences a broader public context, and it placed social sciences and humanities at the centre of public-interest research. In doing so, Strategy AV21 transformed interdisciplinarity from an abstract ideal into a practical architecture of knowledge. It showed that the modern Academy could remain faithful to its classical commitment to rigorous research while becoming a more integrated, responsive, and publicly meaningful national knowledge institution.

Thematic Programmes of Strategy AV21

1. Energy, Climate, Environment, and Sustainability

Energy, climate, environment, and sustainability formed one of the most natural thematic cores of Strategy AV21 because they concentrated several of the most urgent public-interest challenges facing the Czech Republic and the wider world. These themes were not chosen only because they were politically visible or internationally fashionable. They expressed a deeper transformation in the relationship between science, society, and the conditions of life. Energy systems determine the functioning of industry, households, transport, digital infrastructures, hospitals, schools, and public administration. Climate change alters landscapes, water regimes, agriculture, forests, biodiversity, urban life, and risk patterns. Environmental degradation affects health, food systems, regional development, and the quality of life of future generations. Sustainability, therefore, was not a separate programme topic added to the Academy's portfolio; it became a way of thinking about the long-term responsibility of knowledge itself (*Czech Academy of Sciences, 2017*; *United Nations, 2015*).

The Academy's engagement with these themes drew on a wide range of its scientific capacities. Physics, chemistry, materials science, plasma research, geology, atmospheric physics, hydrology, ecology, botany, soil science, biology, mathematics, computer modelling, economics, sociology, law, and public policy all had something to contribute. Strategy AV21 made this diversity visible by framing energy and sustainability as public-interest problems rather than as narrow technical sectors. In a classical disciplinary arrangement, energy might appear mainly as a matter for physics and engineering, climate as a matter for atmospheric science, environment as a matter for ecology, and sustainability as a policy slogan. Under Strategy AV21, these areas were connected. The result was a more integrated understanding of the material, technological, social, and political foundations of contemporary civilisation.

The energy question was especially important because the Czech Republic inherited an industrial economy with strong dependence on reliable power supply, heavy manufacturing, heat production, transport infrastructures, and technologically demanding sectors. Energy is not merely a commodity in such a society; it is a condition of social order and economic continuity. The transition away from high-emission systems therefore cannot be treated as a simple replacement of one source by another. It involves investment cycles, technological innovation, public acceptance, grid stability, storage capacity, regional employment, price vulnerability, and geopolitical dependence. Strategy AV21's programme on sustainable energy addressed this complexity by connecting research on low-emission sources, nuclear safety, renewable systems, hydrogen, energy storage, circular economy, and decentralised energy. Its importance lay in showing that energy transition is a scientific, technical, economic, environmental, and social process at the same time (*Czech Academy of Sciences, n.d.*).

The phrase "sustainable energy" itself carried a double meaning. It referred to energy systems that reduce environmental burden, but also to systems capable of supporting society reliably over time. Sustainability cannot mean only lowering emissions if the result is unstable supply, unaffordable prices, or social rejection. Conversely, reliability cannot be defended indefinitely

through systems that damage the climate, pollute the environment, or lock society into vulnerable dependencies. Strategy AV21 placed the Academy in the middle of this difficult balance. Its role was not to provide political slogans for or against any single energy source, but to produce knowledge about the conditions, limits, risks, and possibilities of transition. This gave the Academy a voice in one of the most consequential debates of the 21st century.

Nuclear energy occupied a particular place in this discussion. The Czech Republic has long treated nuclear power as part of its energy mix, and any realistic debate on decarbonisation, energy security, and industrial continuity must consider it. Strategy AV21's attention to nuclear systems, reactor safety, thermonuclear fusion, materials, and energy conversion reflected the Academy's capacity to work on technically demanding questions with long time horizons. Nuclear research is not only a matter of power generation; it involves safety culture, ageing infrastructures, waste, public trust, regulation, and international cooperation. The Academy's scientific independence was crucial here because nuclear debates are often politically charged. Public-interest research in this field requires both technical seriousness and an ability to communicate uncertainty responsibly.

Renewable energy created a different set of research problems. Solar, wind, biomass, geothermal, and other renewable sources are essential for low-emission transition, but their integration into real energy systems raises questions of intermittency, storage, decentralisation, grid management, land use, materials, recycling, and local acceptance. Strategy AV21's energy agenda therefore had to include not only production, but also storage, conversion, distribution, and social impact. This is where chemistry, materials science, electrochemistry, computer modelling, systems engineering, environmental assessment, and social research meet. A renewable system is not sustainable simply because the source is renewable. It becomes sustainable only when the whole chain of production, infrastructure, maintenance, environmental cost, and public use is understood.

Hydrogen technologies illustrated the same logic. Hydrogen is often presented as a promising energy carrier for transport, industry, storage, and future low-carbon systems. Yet its real contribution depends on how it is produced, stored, transported, and used. It may support decarbonisation if produced through low-emission processes, but it may also reproduce old dependencies if tied to fossil sources or inefficient infrastructures. Strategy AV21's inclusion of hydrogen research therefore reflected the Academy's effort to study emerging technologies before they become fixed in policy or industrial practice. This anticipatory role is one of the reasons a national academy matters. It can investigate options before political urgency narrows the range of possible choices.

Energy storage was another central issue because the transition to renewable and decentralised systems depends on the capacity to manage uneven production and consumption. Batteries, hydrogen, thermal storage, mechanical systems, and chemical storage each involve different materials, efficiencies, costs, environmental burdens, and technological risks. Research on storage connects fundamental chemistry and physics with engineering, economics, and sustainability assessment. It also links national energy security with global supply chains for critical materials. Strategy AV21's energy programmes therefore did not simply follow the rhetoric of green transition. They examined the material and infrastructural foundations on which such a transition must rest.

Climate change gave the environmental dimension of Strategy AV21 a planetary horizon. The Academy's work in atmospheric research, climatology, hydrology, ecology, geology,

mathematics, and modelling allowed it to contribute to understanding climate processes and their local consequences. For the Czech Republic, climate change is not an abstract global trend. It appears in drought, heat waves, changing precipitation, forest stress, soil degradation, flood risk, agricultural uncertainty, urban heat islands, and biodiversity shifts. These processes affect regions differently and require knowledge at multiple scales. Strategy AV21's climate-related orientation therefore connected global science with national adaptation needs (*Intergovernmental Panel on Climate Change, 2023*).

The environmental challenge was not reducible to climate alone. Biodiversity loss, ecosystem fragmentation, soil depletion, water pollution, invasive species, landscape homogenisation, and unsustainable land use are problems with their own dynamics. Strategy AV21's programmes on biodiversity, land conservation, food systems, and ecosystems reflected this broader understanding. The Academy's biological and environmental institutes had accumulated long-term expertise in Czech landscapes, species, habitats, forests, wetlands, rivers, agricultural ecosystems, and protected areas. Such knowledge is essential because environmental policy without empirical grounding easily becomes declarative. The Academy could provide the long memory of ecosystems: data, collections, monitoring, field observations, and historical comparisons that reveal change over time (*Czech Academy of Sciences, n.d.*; *Czech Academy of Sciences, n.d.*).

The programme on the global biodiversity crisis was particularly important because biodiversity is often perceived as a specialised ecological concern, while in reality it affects the stability of food systems, water cycles, disease patterns, climate resilience, cultural landscapes, and human wellbeing. Biodiversity loss is not only the disappearance of species from scientific catalogues. It is the weakening of ecological relations that support agriculture, pollination, soil fertility, pest control, and landscape resilience. Strategy AV21 treated biodiversity as a public-interest problem by connecting researchers with government and civic society. This communication platform was essential because biodiversity policy requires cooperation among scientists, landowners, municipalities, farmers, conservation authorities, educators, and citizens. The Academy's role was to make the complexity of life systems politically and socially intelligible.

The Czech landscape became a central object of sustainability research because it carries the traces of geology, agriculture, settlement, industrialisation, socialist planning, post-socialist transformation, and contemporary climate pressure. Landscape is never only nature; it is nature shaped by history, property, infrastructure, labour, memory, and policy. Strategy AV21's attention to land conservation and restoration showed that environmental research must deal with this layered reality. Restoring a landscape means understanding soils, water, vegetation, species, erosion, farming practices, legal frameworks, local communities, and economic incentives. It also means recognising that landscapes are cultural spaces in which people live, work, remember, and imagine their future.

Water was one of the most sensitive dimensions of this landscape problem. Droughts, floods, groundwater depletion, river regulation, wetland loss, soil retention, and urban water management all became increasingly important for Czech environmental policy. Scientific research in hydrology, climatology, geology, soil science, ecology, and modelling helps society understand where water is stored, how it moves, how it is lost, and how it can be retained. But water management also depends on municipalities, agriculture, construction, law, public investment, and citizen behaviour. Strategy AV21's interdisciplinary architecture was therefore

well suited to this field. It allowed water to be seen not as a technical resource alone, but as a central element of environmental resilience.

Food production connected energy, climate, biodiversity, soil, health, and social behaviour. Strategy AV21's programme on sustainable food production and consumption addressed one of the most ordinary and fundamental public-interest questions: how societies feed themselves without destroying the ecological conditions of future food production. Food systems involve crop breeding, plant biology, microbiology, soil quality, water availability, food chemistry, processing, logistics, nutrition, waste, consumer habits, and public health. Climate change and intensive agriculture place additional pressure on yields and soil fertility. At the same time, unhealthy diets and food waste create social and medical consequences. Strategy AV21 placed food within an integrated sustainability frame rather than treating it as an agricultural issue alone (*Czech Academy of Sciences, n.d.*).

This was important because food security is often misunderstood as the mere availability of calories. In modern societies, food security also concerns quality, nutrition, safety, affordability, environmental footprint, resilience of supply chains, and cultural habits of consumption. The Academy's research could contribute through plant science, genetics, chemistry, microbiology, environmental analysis, economics, public health, and social research. Sustainable food systems require knowledge about both production and consumption. They ask how crops can become more resistant, how soils can be protected, how contaminants can be reduced, how diets affect health, and how waste can be limited. Strategy AV21's programme format allowed these questions to be treated as connected.

Circular economy appeared within the energy and sustainability agenda as a response to the limits of linear production and consumption. A society that extracts, produces, uses, and discards materials without systematic recovery creates environmental pressure, energy waste, pollution, and dependence on raw materials. Circular approaches require research on materials, waste processing, recycling technologies, industrial design, chemical transformation, regulation, consumer behaviour, and economic incentives. Strategy AV21's inclusion of circular economy within energy-related research showed that sustainability is not only about replacing energy sources. It is also about changing material flows. The Academy's chemical, technological, environmental, and social expertise could help define what circularity means in practice rather than as a fashionable slogan.

Sustainability also raised the question of the Academy's own operations and institutional culture. Research institutions consume energy, operate buildings, travel, use laboratories, purchase equipment, and generate waste. Although Strategy AV21 primarily concerned research programmes, the broader movement towards ecological responsibility also affected how academic institutions thought about themselves. A public-interest research institution cannot speak credibly about sustainability if it ignores its own environmental footprint. This does not mean that research must be paralysed by operational constraints, but it does require reflexivity. The Academy's sustainability agenda therefore had both external and internal dimensions: producing knowledge for society and considering the conditions under which knowledge production itself remains responsible.

The climate and sustainability programmes also sharpened the Academy's relationship with public policy. Energy transition, biodiversity protection, climate adaptation, food systems, and landscape restoration require decisions by ministries, municipalities, regions, regulatory bodies, companies, and citizens. Scientific knowledge cannot replace these decisions, but it

can improve them. It can show risks, compare scenarios, explain trade-offs, identify unintended consequences, and reveal long-term patterns that are invisible in short political cycles. Strategy AV21's programme-based format made this policy relevance more systematic. It allowed the Academy to communicate with decision-makers through organised thematic platforms rather than isolated expert interventions.

At the same time, public-interest research in sustainability must remain independent because environmental and energy debates are full of conflicting interests. Industrial actors, political parties, municipalities, environmental organisations, farmers, households, and consumers may all define the public good differently. A national academy must not become the voice of one interest group. Its contribution lies in methodological discipline, long-term knowledge, and the capacity to expose complexity. Strategy AV21 gave the Academy an institutional framework for entering contested debates while preserving scientific authority. This balance between engagement and independence was essential for credibility.

Communication was especially important in climate and sustainability research because these fields are vulnerable to misunderstanding, simplification, and politicisation. Climate science deals with probabilities, models, scenarios, uncertainties, and long time horizons. Biodiversity research deals with invisible dependencies and slow losses. Energy transition deals with trade-offs between cost, security, emissions, and public acceptance. Food sustainability deals with everyday habits as well as global systems. Strategy AV21's public-interest mission required the Academy to explain these issues in a credible and broader context. Scientific communication became part of the sustainability agenda itself.

The social sciences were indispensable in this communication task. Public acceptance of energy technologies, climate measures, conservation policies, or dietary changes cannot be assumed. It depends on trust, fairness, identity, economic burden, regional experience, political culture, and the perceived legitimacy of institutions. A technically correct policy may fail if it is socially blind. Strategy AV21's integration of social research into energy and sustainability programmes therefore prevented a purely technocratic approach. It allowed the Academy to ask not only what should be done in technical terms, but also how society can understand, negotiate, and implement change.

The humanities also had a role in this thematic block, although it may be less obvious at first glance. Sustainability is partly a question of values, memory, narratives, and the human relationship to place. Landscapes are remembered; rivers, forests, villages, fields, and cities carry cultural meanings. Debates about energy futures are also debates about modernity, comfort, responsibility, sacrifice, and intergenerational justice. Climate change forces societies to rethink their place in nature and their obligations to the future. The humanities help articulate these meanings. Strategy AV21's wider interdisciplinary logic made it possible to include such reflection within the public-interest mission of the Academy.

The energy and sustainability agenda also connected the Academy with European policy frameworks. The European Green Deal, climate neutrality objectives, biodiversity strategies, circular economy policies, and Horizon Europe missions all shaped the context in which Czech research developed. Strategy AV21 allowed the Academy to align with these European priorities while translating them into national scientific and social conditions. This translation was important because European strategies cannot be implemented mechanically in every country. They must be interpreted through national energy systems, landscapes, industries,

institutions, and cultural attitudes. The Academy could serve as one of the institutions capable of this translation (*European Commission, 2019*; *European Commission, 2021*).

The global dimension was equally important. Climate change, biodiversity loss, resource depletion, and food insecurity are planetary processes, but their consequences are experienced locally. The Academy's research therefore had to operate across scales. It could contribute to global science through publications, international collaborations, monitoring networks, and comparative research. At the same time, it had to answer Czech questions about forests, drought, nuclear energy, renewable integration, food production, urban adaptation, and regional resilience. Strategy AV21 gave the Academy a framework in which global and national scales could be connected. This is one of the distinctive tasks of a national academy in an interdependent world.

The sustainability agenda also strengthened the Academy's connection with future generations. Many scientific institutions justify themselves through current outputs, but sustainability requires a longer moral horizon. The effects of energy choices, biodiversity loss, soil degradation, greenhouse gas emissions, and landscape transformation extend beyond the present generation. Strategy AV21's motto, "top research in the public interest", therefore acquired a temporal depth in this thematic area. Public interest does not belong only to today's citizens. It also includes those who will inherit the consequences of today's decisions. This gave the Academy's environmental and energy programmes an ethical significance beyond technical research.

The Academy's strength in this field depended on continuity. Environmental and climate knowledge require long-term observation, repeated measurement, data preservation, and institutional memory. Energy technologies require sustained laboratory work and cumulative engineering experience. Food and biodiversity research require field knowledge, collections, and experimental infrastructures. Such capacities cannot be created quickly in response to a political emergency. Strategy AV21 made visible the importance of maintaining them over time. It showed that public-interest research is often a matter of preparedness: society benefits from scientific capacities that have been cultivated before their necessity becomes obvious.

At the same time, Strategy AV21's sustainability orientation was not pessimistic. It did not present contemporary society only as a source of ecological damage and risk. It also highlighted possibilities: new energy systems, better storage, safer technologies, restored landscapes, resilient food systems, informed policy, public communication, circular economy, and responsible innovation. This constructive dimension mattered because public-interest science should not only diagnose decline. It should help identify realistic pathways of adaptation and transformation. The Academy's role was therefore both critical and creative: to reveal dangers, but also to explore alternatives.

The thematic block of energy, climate, environment, and sustainability also changed the modern image of the Academy. It showed AV ČR as an institution directly engaged with the conditions of everyday life and national future. Energy prices, drought, floods, forests, food, pollution, biodiversity, and climate adaptation are not remote academic topics. They concern households, regions, farmers, schools, industry, health, and public budgets. By organising research around these themes, Strategy AV21 made the Academy more publicly recognisable. It demonstrated that a classical research institution could contribute to urgent social questions without abandoning fundamental science.

This was particularly important after the long post-socialist period in which the Academy had to defend its autonomy, quality, and institutional necessity. Strategy AV21 allowed AV ČR to shift the argument. The Academy did not ask to be supported only because it preserved scientific excellence. It showed that excellence could be mobilised for public problems of high consequence. Energy, climate, environment, and sustainability were ideal fields for this demonstration because they require both deep science and public responsibility. They also require cooperation between institutes, disciplines, sectors, and generations. In this sense, they embodied the whole logic of Strategy AV21.

Thus, the Strategy AV21 programmes connected with energy, climate, environment, and sustainability revealed the Czech Academy of Sciences as a public-interest research institution capable of addressing the material foundations of contemporary society. These programmes showed that energy transition, climate adaptation, biodiversity protection, landscape restoration, sustainable food systems, circular economy, and environmental resilience cannot be solved by isolated disciplines or short-term policy reactions. They require long-term research, interdisciplinary cooperation, public communication, technological imagination, social understanding, and ethical responsibility towards future generations. Strategy AV21 gave the Academy a format through which its natural, technical, social, and human sciences could be assembled around these challenges. In doing so, it transformed sustainability from a policy slogan into an academic mission grounded in scientific excellence and civic responsibility.

2. Health, Society, Security, and Resilience

Health, society, security, and resilience formed another major thematic constellation within Strategy AV21 because they brought the Academy's public-interest mission closest to the vulnerabilities of human life. If the previous thematic block centred on the material and environmental conditions of civilisation, this one focused on the biological, social, institutional, and psychological conditions under which people live, age, trust, cooperate, and survive crises. Health was no longer understood only as the treatment of disease, society no longer only as a field of observation, security no longer only as military or police protection, and resilience no longer only as recovery after disruption. Strategy AV21 placed these concepts in relation to one another. It showed that a modern academy must study disease mechanisms and public policy, gene therapy and social inequality, infectious risks and public communication, demographic change and institutional trust, security technologies and the behaviour of citizens. This thematic block therefore revealed how deeply intertwined biomedical research, social diagnosis, public administration, ethics, communication, and cultural interpretation had become in the 21st century (*Czech Academy of Sciences, 2017*).

The Academy's health-related programmes developed from a strong base in life sciences, chemistry, biomedicine, physiology, molecular biology, immunology, microbiology, pharmacology, and medical technologies. These fields had long been central to the Academy's scientific profile, especially after the post-1993 modernisation of biological and biomedical institutes. Strategy AV21 gave them a broader public frame. It did not present biomedical research only as laboratory excellence or as a source of future therapies, although both aspects remained essential. It connected health research with quality of life, ageing, diagnostics, personalised treatment, prevention, social preparedness, and the capacity of public institutions to respond to risk. This was important because health in contemporary

society is never purely biological. It is also demographic, economic, communicative, political, ethical, and institutional.

One of the most visible examples of this logic was the programme directed towards precision medicine and gene therapy. Precision medicine expresses a major transformation in biomedical thinking: the movement from generalised treatment models towards approaches adapted to molecular mechanisms, genetic information, patient variability, and disease subtypes. Gene therapy adds an even more ambitious horizon because it aims not only to treat symptoms, but to intervene in the biological causes of disease. Such research requires molecular biology, genetics, virology, immunology, bioinformatics, chemistry, nanotechnologies, clinical cooperation, regulatory understanding, and ethical reflection. Strategy AV21 placed this field within the public-interest mission of the Academy because advanced therapy is not only a scientific frontier. It raises questions of accessibility, safety, public trust, cost, social expectation, and the future organisation of healthcare (*Czech Academy of Sciences, n.d.*; *World Health Organization, 2021*).

The public significance of precision medicine lies in its promise and its difficulty. The promise is that patients may receive more accurate diagnoses and more effective treatments, especially in fields such as oncology, rare diseases, immunological disorders, and genetic conditions. The difficulty is that precision medicine depends on complex infrastructures: genomic data, biobanks, specialised laboratories, computational analysis, clinical validation, regulatory pathways, and healthcare systems able to implement new knowledge. The Academy's role is not to replace hospitals or pharmaceutical companies, but to generate the fundamental and translational knowledge without which such medicine cannot develop responsibly. Strategy AV21 thus connected the laboratory with the clinic and the clinic with society. This was precisely the type of bridge that a public-interest academy was expected to build.

Infectious diseases provided another essential dimension of the health agenda. The Strategy AV21 programme on infectious diseases and the earlier programme on virology and antiviral therapy reflected the Academy's capacity to study pathogens, host responses, viral mechanisms, antimicrobial resistance, immune processes, diagnostics, and therapeutic strategies. These fields became even more publicly visible after the COVID-19 pandemic, but their significance had been present long before the pandemic began. Infectious diseases are old companions of humanity, yet they constantly reappear in new ecological, technological, and social contexts. Global travel, urbanisation, environmental change, intensive agriculture, antimicrobial misuse, and social inequality can all shape the spread and impact of infections. Strategy AV21 therefore treated infection not only as a biomedical topic, but as a challenge to collective preparedness (*Czech Academy of Sciences, n.d.; Czech Academy of Sciences, n.d.*).

The pandemic made clear that a virus is a biological entity, but a pandemic is a social event. It affects hospitals, schools, workplaces, families, media, political institutions, borders, supply chains, and public trust. It requires diagnostics, modelling, vaccine research, treatment development, public communication, legal decisions, economic support, and psychological resilience. The Academy's biomedical institutes could contribute through research on viral behaviour, immunity, diagnostics, and therapeutic possibilities, while social scientists and humanists could analyse public response, misinformation, institutional capacity, and the cultural meaning of risk. Strategy AV21's interdisciplinary logic was therefore not an abstract ideal in this field. It corresponded to the real structure of a health crisis.

Public health also demonstrated the limits of purely individualised understandings of medicine. A society may possess advanced therapies and still suffer from poor health outcomes if prevention is weak, inequalities are deep, communication is ineffective, or institutions are distrusted. Quality of life depends on biological health, but also on work, housing, education, social relations, environment, ageing, mental wellbeing, and access to care. Strategy AV21's health themes therefore extended beyond disease as a strictly medical object. They helped frame health as a public condition, shaped by interactions between bodies, technologies, institutions, and ways of life. This expanded understanding was necessary for an Academy that wanted to link scientific excellence with public responsibility.

Ageing was one of the most important social and health-related challenges facing Czech society and Europe more broadly. Longer life expectancy is a success of modern medicine and social development, but it also transforms family structures, pension systems, healthcare demand, labour markets, housing needs, intergenerational relations, and concepts of care. Biomedical research can study ageing at the cellular, molecular, and physiological levels; social sciences can analyse demographic change, care systems, social isolation, and policy responses; humanities can interpret the meaning of ageing, dignity, dependence, memory, and generational identity. Strategy AV21 created a space in which these perspectives could be connected. Ageing thus became not only a medical problem, but a civilisational question about how societies organise longer human lives.

Mental health and psychological resilience also belong to this thematic field, even when they are not always named as separate programme titles. Modern societies face stress from economic uncertainty, digital acceleration, social fragmentation, war, migration, pandemic experience, climate anxiety, and the erosion of stable expectations. Resilience cannot be understood only as the capacity of infrastructure to withstand disruption. It also concerns individuals, communities, institutions, and cultures. The Academy's psychological, sociological, philosophical, and medical expertise can help explain how people cope with uncertainty, how communities maintain solidarity, and how institutions either support or weaken resilience. Strategy AV21's broader social programmes made such questions part of the Academy's public mission.

The programme Resilient Society for 21st Century: Crisis Potentials and Effective Transformation expressed this movement most directly. It shifted the focus from isolated crisis response to the general assumptions of individual and social resilience. Resilience, in this context, does not mean passive endurance or a return to the previous state at any cost. It means the capacity to absorb shocks, learn from disruption, transform institutions, maintain social bonds, and adapt without losing democratic and human values. This is a complex research object. It requires sociology, psychology, political science, philosophy, economics, anthropology, communication studies, history, security studies, and public administration. Strategy AV21 thus placed resilience among the central problems of contemporary knowledge, not as a fashionable keyword, but as an analytical category for societies exposed to continuous uncertainty (*Czech Academy of Sciences, n.d.*).

The Czech experience gave the concept of resilience particular depth. The country had passed through empire, national revival, democratic statehood, occupation, communism, normalisation, the Velvet Revolution, post-socialist transformation, European integration, economic crises, migration debates, pandemic disruption, and the security consequences of Russia's war against Ukraine. Each of these historical layers shaped institutions, public

expectations, trust, memory, and vulnerability. A society's resilience is never only a technical capacity; it is historical. It depends on what people remember, whom they trust, how institutions behaved in previous crises, and how public language frames danger and solidarity. Strategy AV21's integration of social sciences and humanities was therefore indispensable for studying resilience in the Czech context.

The programme Society in Motion and Public Policy added another crucial dimension. Modern society is characterised by rapid change: migration, demographic shifts, labour-market transformation, housing pressures, educational inequalities, technological disruption, public debt, regional disparities, epidemics, wars, and environmental crises. These phenomena are not exceptional interruptions of a stable social order. They increasingly define the normal conditions under which policy must operate. Public policy research becomes essential because societies need evidence about what works, for whom, under what conditions, and with what unintended consequences. Strategy AV21's inclusion of public policy demonstrated that the Academy understood governance itself as a field requiring scientific analysis (*Czech Academy of Sciences, n.d.*).

This was significant for the Academy's modern role. In the socialist period, social sciences were often constrained by ideology, and public policy was largely subordinated to central planning and political doctrine. After 1989, Czech social sciences had to rebuild empirical methods, international connections, and intellectual independence. Strategy AV21 represented a later stage in which social sciences could contribute confidently to democratic governance. They could analyse public policies without serving as instruments of ideological control. They could help the state understand social reality while preserving critical autonomy. This was one of the clearest examples of the Academy's transformation from a state-directed institution into a democratic knowledge institution.

Security, in this thematic block, must be understood broadly. It includes biological security, cyber security, energy security, social cohesion, protection against disinformation, resilience of institutions, food and health security, and the ability of society to respond to war-related and environmental shocks. Strategy AV21 did not turn the Academy into a security agency. Rather, it placed security within the wider domain of knowledge, preparedness, and public trust. Scientific institutions contribute to security by identifying risks, modelling consequences, developing technologies, analysing vulnerabilities, and explaining complex threats. This is especially important in societies where risks are hybrid and where physical, digital, biological, social, and cultural dimensions overlap.

The war in Ukraine and the wider destabilisation of European security after 2022 intensified the relevance of this approach. Even when Strategy AV21 programmes were not designed as geopolitical instruments, the Academy's research on society, identity, resilience, communication, energy, security, and public policy became more visibly connected with national preparedness. War affects energy supply, migration, inflation, public discourse, defence thinking, historical memory, and trust in institutions. It also produces disinformation and identity conflicts. A national academy cannot decide foreign policy, but it can help society understand the structural consequences of war and uncertainty. Strategy AV21's social and security-related programmes made this contribution more coherent.

Disinformation and communication risks formed a particularly important part of social security. The digital environment changed the circulation of knowledge, rumour, fear, propaganda, expertise, and political mobilisation. Public health crises, elections, migration

debates, wars, climate change, and technological controversies are all affected by communication systems. A society may possess excellent scientific knowledge and still fail if that knowledge cannot be communicated or trusted. Strategy AV21's programmes on communication, society, resilience, and artificial intelligence therefore belong indirectly to the health and security agenda as well. They show that security in the 21st century includes the integrity of public discourse.

Trust became one of the most important hidden variables in this thematic block. Trust in scientists, doctors, public institutions, media, courts, schools, and democratic procedures affects how societies respond to crises. During a pandemic, trust influences whether citizens follow health guidance. During energy transition, it shapes acceptance of infrastructure and policy costs. During security crises, it affects resistance to disinformation. During social reform, it determines whether citizens believe institutions are acting fairly. The Academy's public-interest mission therefore cannot be separated from the production of trustworthy knowledge. Strategy AV21 strengthened this mission by making Academy research more visible, coordinated, and publicly oriented.

The social dimension of health also raised questions of inequality. Health risks are not distributed evenly across society. Income, education, region, age, gender, occupation, housing, ethnicity, disability, and access to services all influence exposure and outcome. Public policy research can reveal these differences and help design better interventions. Biomedical research may produce powerful tools, but without social analysis those tools may benefit groups unevenly or fail to reach those most in need. Strategy AV21's integration of health and society therefore protected the Academy from a narrow biomedical model. It encouraged a more complete understanding of how disease, care, inequality, and policy interact.

Resilience also has a regional dimension. The Czech Republic is not socially homogeneous. Prague, Brno, industrial regions, rural municipalities, borderlands, university towns, post-industrial areas, and ageing localities experience risks differently. Health infrastructure, economic opportunities, social trust, educational access, and environmental pressures vary across space. A national academy has the capacity to connect local evidence with national interpretation. Strategy AV21's public policy and resilience themes allowed research to address regional differences without reducing them to administrative statistics. This spatial sensitivity is important because crises often reveal territorial inequalities that remain invisible in national averages.

The Academy's humanities institutes contributed to this theme by analysing memory, identity, language, ethics, and historical experience. Security and resilience are not only about resources and institutions; they are also about meanings. Societies interpret danger through historical analogies, collective memories, national narratives, moral vocabularies, and cultural fears. The memory of authoritarianism, occupation, normalisation, or transition can influence how citizens respond to state measures, propaganda, solidarity appeals, or external threats. Strategy AV21's inclusion of humanities within public-interest research made it possible to understand these deeper dimensions. Without them, resilience would be reduced to management technique.

Ethics was particularly important in health and security research. Gene therapy, assisted reproduction, infectious disease measures, surveillance technologies, artificial intelligence, data sharing, and crisis governance all raise ethical questions. What risks are acceptable? Who

decides? How should personal data be protected? How should benefits and burdens be distributed? How can emergency measures remain compatible with rights and dignity? Strategy AV21's interdisciplinary structure allowed ethical reflection to accompany scientific and technological development. This was necessary because public-interest research must be not only effective, but also legitimate.

Assisted reproduction, as one of the Strategy AV21 programme themes, shows how closely biomedical progress can be connected with social, ethical, and demographic questions. Infertility treatment is a medical field, but it also touches family formation, gender, kinship, legal regulation, psychological stress, religious and moral debates, ageing parenthood, and demographic change. The Czech Republic has a developed assisted reproduction sector, which makes the topic socially relevant as well as scientifically significant. Strategy AV21's attention to the future of assisted reproduction therefore belongs to the broader health-society nexus. It demonstrates that the Academy's public-interest research can address intimate human problems while maintaining scientific distance and ethical seriousness (*Czech Academy of Sciences, n.d.*).

The fungal programme within Strategy AV21 also illustrates the combination of threat and opportunity. Fungi may be pathogens affecting humans, animals, plants, and agriculture; they may also be sources of new compounds, ecological processes, biotechnology, food, and materials. This duality is typical of many modern biological challenges. The same domain of life can generate disease risks and innovation potential. Studying fungi therefore requires microbiology, ecology, medicine, agriculture, chemistry, biotechnology, and environmental science. Within the broader theme of health, society, security, and resilience, such research shows how biological knowledge can contribute both to risk prevention and to new forms of sustainable innovation (*Czech Academy of Sciences, n.d.*).

The concept of systemic risk helps to connect these diverse examples. A systemic risk is one in which disruption spreads across interconnected systems: health, economy, education, supply chains, communication, governance, and social trust. The pandemic was a systemic risk; so are energy shocks, cyberattacks, climate disasters, financial crises, and war-related disruptions. Strategy AV21's thematic programmes were well suited to such risks because they were not confined to single disciplines. They allowed the Academy to study how crises move through society and how institutions can reduce vulnerability. This systemic understanding is one of the most important contributions of public-interest research in the 21st century (*Renn, 2008*).

Preparedness, however, must not be confused with prediction. Science cannot predict every crisis in detail, and public institutions cannot eliminate uncertainty. What research can do is improve the quality of preparedness by identifying patterns, vulnerabilities, thresholds, possible scenarios, and conditions of resilience. Strategy AV21 supported this kind of anticipatory knowledge. It did not promise certainty. It strengthened the capacity of society to think before crisis, learn during crisis, and transform after crisis. This is a mature form of scientific responsibility because it recognises both the power and the limits of expertise.

The Academy's public communication became especially significant in this thematic block because health, security, and resilience are areas where fear can easily dominate reasoned discussion. During epidemics, people fear illness and death; during security crises, they fear war and instability; during social change, they fear loss of status, identity, or control. Scientific communication must therefore be accurate, calm, transparent, and aware of public emotion.

Strategy AV21 helped the Academy frame its communication around recognisable social problems rather than isolated disciplinary outputs. It allowed researchers to explain why their work mattered for the protection and improvement of life.

At the same time, public-interest communication in these fields must avoid paternalism. Citizens are not merely passive recipients of expert instruction. They possess experience, local knowledge, moral concerns, and legitimate questions. A democratic research institution must communicate with them, not only at them. Strategy AV21's orientation towards society, public policy, and resilience opened the possibility of more dialogic forms of expertise. The Academy could present evidence, but also learn from the way social actors experience risk and change. This did not weaken scientific authority; it made authority more socially intelligent.

The health and resilience agenda also linked Strategy AV21 with international organisations and global debates. The World Health Organization's work on health systems, pandemic preparedness, antimicrobial resistance, and social determinants of health; the OECD's work on resilience and public governance; and European research programmes on health, security, and social transformation all formed part of the broader context. The Academy's programmes allowed Czech research to participate in these debates from a national institutional position. Strategy AV21 thus mediated between global health and security concerns and the specific needs of Czech society. This mediation is one of the classical functions of a national academy in a globalised world (*Organisation for Economic Co-operation and Development, 2019; World Health Organization, 2021*).

The Academy's role in this thematic field was also strengthened by its ability to work across temporal scales. Biomedical research may operate in the timescale of experiments, clinical development, and therapeutic innovation. Social resilience may require historical comparison and long-term observation of institutions. Public policy evaluation may analyse the effects of reforms over years or decades. Security risks may emerge suddenly but reflect accumulated vulnerabilities. Strategy AV21's programme format allowed these different temporalities to coexist. It showed that public-interest research must combine rapid response with long memory.

The connection between health and society also made Strategy AV21 relevant to education and the formation of public competence. Citizens need scientific literacy, media literacy, health literacy, and civic literacy to navigate crises. Schools, universities, museums, media, and public institutions all participate in this process. The Academy, though not a university in the full teaching sense, contributes through expert communication, doctoral training, public lectures, science festivals, publications, and cooperation with educational institutions. Strategy AV21 made these communicative and educational functions more visible. Health and resilience are not produced only in hospitals and ministries; they are also produced through knowledge, understanding, and trust.

This thematic block also revealed the Academy's capacity to integrate vulnerability and innovation. Health programmes looked towards new therapies, diagnostics, and biomedical technologies. Social programmes examined policy, crisis potential, identity, and resilience. Security-related questions connected risk analysis with communication and technological preparedness. These are not separate worlds. Innovation can reduce vulnerability, but it can also create new risks. Vulnerability can stimulate research, but it can also expose social inequalities. Strategy AV21 provided a structure in which these relationships could be analysed rather than simplified.

The modern public image of the Academy benefited from this field because health, society, security, and resilience are immediately understandable to citizens. People may not always understand the internal structure of AV ČR, but they understand illness, ageing, fear, crisis, trust, policy failure, social instability, and the need for protection. By addressing these topics, Strategy AV21 brought the Academy closer to everyday life. It showed that academic research is not remote from human concerns. At the same time, it demonstrated that everyday concerns often require highly specialised knowledge. This is the essence of public-interest science: it connects the ordinary vulnerability of human life with the extraordinary depth of organised research.

Thus, the Strategy AV21 programmes connected with health, society, security, and resilience showed the Czech Academy of Sciences as an institution capable of responding to the human and institutional vulnerabilities of contemporary civilisation. They linked biomedical research with public health, gene therapy with ethics, infectious diseases with social preparedness, public policy with democratic governance, security with communication, and resilience with historical memory and social trust. This thematic block demonstrated that the Academy's public-interest mission could not be reduced to technology or environmental sustainability alone. It also had to address bodies, communities, institutions, values, fears, and capacities for collective adaptation. Strategy AV21 therefore transformed health and resilience into broad interdisciplinary fields in which natural, technical, social, and human sciences could work together for the protection, understanding, and renewal of society.

3. Technologies, Digitalisation, Materials, and Future Industries

Technologies, digitalisation, materials, and future industries formed one of the most forward-looking thematic clusters of Strategy AV21. If the environmental programmes addressed the conditions of planetary and national sustainability, and the health and resilience programmes addressed the vulnerabilities of bodies and societies, this cluster focused on the technological foundations of the future. It asked how a national academy could contribute to a world shaped by artificial intelligence, data, automation, sensors, advanced materials, quantum technologies, diagnostics, photonics, space research, and new industrial processes. These were not only technical topics. They were questions about sovereignty, competitiveness, public trust, security, employment, education, infrastructure, and the place of small and medium-sized countries in global technological change. Strategy AV21 therefore treated technology not as an external application of science, but as one of the central terrains on which scientific autonomy, national capacity, and public interest meet (*Czech Academy of Sciences, 2017*; *Czech Academy of Sciences, n.d.*).

The Academy's technological orientation had deep roots in its post-war and post-socialist history. The Czechoslovak Academy of Sciences had developed strong schools in physics, chemistry, mathematics, cybernetics, materials research, instrumentation, plasma physics, and technical sciences, although these fields were often shaped by the priorities and constraints of the socialist state. After 1989, their development depended increasingly on international evaluation, European projects, competitive funding, and cooperation with universities and industry. Strategy AV21 gave these capacities a new public language. It did not present them only as specialised research traditions, nor only as sources of patents or industrial partnerships. It placed them within a broader question: how can top-level research

help the Czech Republic participate actively in technological transformation rather than merely consume technologies developed elsewhere?

Digitalisation became one of the most important answers to this question. The early Strategy AV21 programme on the hopes and risks of the digital era already captured the double character of digital transformation. Digital technologies make it possible to process data, model complex systems, automate tasks, connect institutions, improve diagnostics, preserve memory, and open new forms of communication. At the same time, they create risks of surveillance, data misuse, cyber vulnerability, misinformation, social fragmentation, labour disruption, and dependence on foreign platforms. The Academy therefore did not treat digitalisation as simple progress. It treated it as a field where mathematics, computer science, social analysis, legal reasoning, ethics, communication studies, and public policy must interact. This balanced approach was essential for a public-interest research institution (*Czech Academy of Sciences, 2017*).

Artificial intelligence intensified the significance of this digital agenda. The programme AI: Artificial Intelligence for Science and Society reflected the fact that AI had become both a research instrument and a social force. It could accelerate discovery, automate analysis, support modelling, improve diagnostics, assist language technologies, optimise industrial processes, and transform scientific instrumentation. Yet it also raised questions of explainability, accountability, bias, privacy, labour, education, security, and democratic control. Strategy AV21's treatment of AI therefore had to be broader than a technical programme in machine learning. It had to ask how AI changes science itself, how it affects society, and how the Academy can help build trustworthy and useful AI systems. This placed AV ČR within a global debate on AI as both technological infrastructure and public concern (*Czech Academy of Sciences, n.d.*; *Organisation for Economic Co-operation and Development, 2019*).

The phrase "for science and society" was especially important in the AI programme. It suggested that artificial intelligence should not be understood only as a commercial technology or a geopolitical race. For the Academy, AI was also a tool for research: a way to analyse complex data, detect patterns, model systems, process language, and support discovery in physics, chemistry, biology, medicine, climate research, social sciences, and the humanities. At the same time, AI was an object of research because it reshaped institutions, communication, law, ethics, and human behaviour. Strategy AV21 therefore placed AI in a dual position. It was both a means of producing knowledge and a phenomenon that itself required critical knowledge.

This dual position made the Academy's role particularly important. Commercial actors often develop AI systems with strong incentives towards speed, market penetration, and proprietary advantage. Governments may approach AI through regulation, security, public services, and economic strategy. Universities contribute through education and research, but they are often distributed across faculties and disciplines. A national academy can provide something different: long-term, interdisciplinary, independent expertise that connects technical competence with social understanding. Strategy AV21 created a framework for precisely this kind of contribution. It allowed AV ČR to study AI without surrendering the topic either to market enthusiasm or to cultural anxiety.

The broader European context reinforced the importance of this agenda. The European Union's digital decade policy set measurable targets for connectivity, digital skills, digitalisation of

business, and digital public services, while the AI and data debates increasingly emphasised trustworthiness, human rights, competitiveness, and strategic autonomy (*European Commission, 2023*; *Organisation for Economic Co-operation and Development, 2019*). Strategy AV21 allowed the Czech Academy to connect national research capacities with these European priorities. The Czech Republic could not define the global technological order by itself, but it could cultivate knowledge and institutions that allowed it to participate more actively. In this sense, digitalisation under Strategy AV21 was not only a technical modernisation theme. It was part of a wider question of European and Czech technological agency.

The programme Breakthrough Technologies for the Future carried this agency-oriented logic even further. It brought together sensing, digitisation, artificial intelligence, quantum technologies, and related technological platforms. Such a programme reflected the recognition that future industries are no longer built from isolated inventions. They depend on convergent technological systems: sensors generate data, digital infrastructures transmit and store them, AI analyses them, quantum technologies may transform computation and measurement, and advanced instruments make it possible to observe phenomena at new scales. Strategy AV21's programme format was well suited to such convergence because it could connect researchers from several institutes and fields. It showed that future technologies emerge from networks of knowledge rather than from one discipline alone (*Czech Academy of Sciences, n.d.*).

Sensing technologies occupied a special position in this cluster because measurement is one of the basic acts of modern science and industry. To measure more precisely is often to discover more deeply. Sensors, detectors, imaging systems, spectroscopic methods, microscopy, and diagnostic instruments make invisible processes visible. They support medicine, environmental monitoring, industrial control, space research, security, materials development, and cultural heritage preservation. The Academy's institutes dealing with scientific instruments, photonics, electronics, physics, chemistry, biology, and engineering could therefore contribute to many public-interest fields through advances in measurement. Strategy AV21 made this contribution more visible by placing instrumentation within a broader technological future.

The earlier programme on diagnostic methods and techniques belongs to the same intellectual family. Diagnostics is often associated with medicine, but its meaning is broader. It includes the detection and interpretation of signals in biological systems, materials, industrial processes, environmental samples, artworks, historical objects, and physical phenomena. A diagnostic technology can identify disease, reveal material defects, monitor pollution, analyse food quality, examine cultural artefacts, or improve industrial reliability. Strategy AV21 therefore treated diagnostic methods as a cross-cutting field where basic research, instrumentation, data analysis, and application meet. This made diagnostics one of the bridges between the Academy's laboratories and society's practical needs (*Czech Academy of Sciences, 2017*).

Photonics and light-based technologies also carried strategic importance. The programme Light at the Service of Society captured the public-interest meaning of research on lasers, optics, imaging, spectroscopy, photonic materials, and light-matter interaction. Light-based technologies are essential in medicine, telecommunications, manufacturing, environmental monitoring, cultural heritage analysis, defence, and scientific instrumentation. They are often

invisible to citizens because they operate inside devices and infrastructures, yet modern life depends heavily on them. Strategy AV21 allowed the Academy to show that highly specialised optical and photonic research can serve society in concrete ways. It also demonstrated how fundamental physics can generate technological platforms with broad industrial and public consequences.

Advanced materials formed another core of this thematic cluster. The early Strategy AV21 programme on new materials based on metals, ceramics, and composites addressed a field in which fundamental science, industrial capacity, and future technologies are closely intertwined. Materials determine what can be built, stored, transported, protected, implanted, miniaturised, recycled, or made more efficient. Energy systems need better batteries, catalysts, heat-resistant components, and materials for hydrogen technologies. Medicine needs biocompatible materials, carriers, implants, sensors, and diagnostic platforms. Transport, construction, electronics, aerospace, defence, and environmental technologies all depend on materials with specific properties. Strategy AV21 therefore placed materials research at the centre of future industry rather than treating it as an auxiliary technical discipline (*Czech Academy of Sciences, 2017*).

The strategic relevance of advanced materials increased further as Europe began to emphasise green and digital transitions, supply-chain security, and industrial leadership. Advanced materials are not only scientific objects; they are enabling technologies. They make possible new energy storage, lighter transport, more efficient electronics, better insulation, stronger infrastructure, and more sustainable production. The European Commission's communication on advanced materials for industrial leadership in 2024 reflected the growing recognition that research and innovation in this field are crucial for European competitiveness and resilience (*European Commission, 2024*). Strategy AV21 had already placed the Czech Academy in a position to contribute to this agenda through its long-standing expertise in physics, chemistry, materials science, engineering, and modelling.

Materials research also showed why future industries cannot be separated from sustainability. A new material is not automatically a public good. It may require rare raw materials, energy-intensive production, difficult recycling, or environmentally harmful processes. The public-interest perspective therefore requires evaluation across the whole life cycle: discovery, synthesis, production, use, repair, reuse, recycling, and disposal. Strategy AV21's broader connection between materials, energy, circular economy, and environmental responsibility made this life-cycle perspective more plausible. The Academy could help design materials not only for performance, but also for sustainability, safety, and long-term social value.

The relationship between materials and digitalisation became increasingly close. Machine learning and data-driven approaches now influence the discovery of materials, prediction of properties, optimisation of synthesis, and analysis of experimental results. Scientific AI can accelerate the search for new compounds, catalysts, polymers, alloys, ceramics, and nanostructures. At the same time, AI depends on materials: semiconductors, sensors, memory systems, cooling technologies, batteries, and photonic components. Strategy AV21's technological cluster therefore revealed a feedback loop between digital and material infrastructures. Digital tools transform materials research, while materials research enables the next generation of digital technologies.

Quantum technologies belonged to the most advanced part of this future-oriented agenda. Quantum sensing, quantum communication, quantum computation, and quantum materials

all demand deep theoretical and experimental competence. They also have potential implications for cybersecurity, measurement, simulation, and industrial innovation. For a country such as the Czech Republic, participation in quantum research is not merely a prestige issue. It concerns the ability to remain connected to a technological field that may reshape scientific and economic infrastructures. Strategy AV21's inclusion of quantum technologies within breakthrough technologies showed that the Academy understood future industries as fields requiring early and sustained research engagement, even before applications become routine.

Space research and space-related technologies extended the same logic beyond the Earth's immediate industrial landscape. The Strategy AV21 programme Space for the Mankind presented space not as a remote curiosity, but as a field with implications for observation, communication, navigation, climate monitoring, instrumentation, materials, plasma physics, astronomy, and international cooperation. Space technologies support everyday services, but they also shape security, environmental knowledge, disaster response, and scientific discovery. The Academy's astronomical, physical, atmospheric, geophysical, and technological institutes could contribute to this field through instruments, models, observations, and data analysis. Strategy AV21 therefore integrated space research into the public-interest horizon of future technologies.

The technological cluster also included research on systems for nuclear power industry and energy-related technologies, which connect directly with future industrial capacity. Nuclear systems require materials able to withstand extreme conditions, plasma research relevant to fusion, safety analysis, geophysics, reactor physics, modelling, and the training of specialists. The public-interest importance of such research lies not only in energy production, but also in safety, expertise, strategic autonomy, and the ability of national institutions to understand technologies that have long-term consequences. Strategy AV21's inclusion of social aspects of nuclear power also showed that future industries must be socially understood, not only technically developed (*Czech Academy of Sciences, 2017*).

Future industries depend on this combination of scientific depth and social interpretation. Industrial transformation is often described through terms such as Industry 4.0, automation, smart manufacturing, robotics, cyber-physical systems, and digital twins. Yet these terms can become empty if they are detached from research infrastructures, skilled people, materials, data, standards, and institutional cooperation. The Academy's role under Strategy AV21 was to provide the knowledge base from which such transformation could become more than imported terminology. It could support Czech industry through research on materials, sensors, computation, diagnostics, energy systems, optics, biotechnology, and data analysis. At the same time, it could help analyse the social consequences of industrial transformation.

The labour dimension of future industries is especially important. Automation and AI may increase productivity, but they also transform skills, employment patterns, professional identities, education, and regional economies. Technological change can create new opportunities while deepening inequalities if institutions do not adapt. Strategy AV21's integration of technical research with social sciences made it possible to study this transformation more responsibly. Future industry is not only about machines and processes. It is also about workers, schools, companies, regions, regulation, and the distribution of benefits. A public-interest academy must ask how technological innovation affects society, not only how society can use technological innovation.

Digitalisation also changed the humanities and cultural sciences. Digital archives, computational linguistics, text mining, image analysis, geospatial tools, digitised collections, and virtual reconstructions transformed the ways in which memory, language, literature, archaeology, and art history could be studied. Strategy AV21's technological agenda therefore did not belong exclusively to natural and technical sciences. It affected the whole Academy. The digital era changed how knowledge is stored, searched, visualised, communicated, and preserved. This made digitalisation a common infrastructure of research across disciplinary boundaries.

The public-interest meaning of digital heritage is particularly significant for the Czech Academy. Historical documents, language corpora, museum collections, archaeological records, manuscripts, photographs, and audio-visual materials are part of cultural memory. Digital technologies can preserve and make them accessible, but they also raise questions of selection, interpretation, authenticity, sustainability, and public use. Strategy AV21's combination of digital and memory-related programmes allowed the Academy to understand technology as a tool of cultural continuity as well as industrial innovation. This broadened the concept of future industries by linking it with future memory.

The technological cluster also required attention to security. Digital infrastructures can be attacked, manipulated, or made dependent on external suppliers. AI systems can produce errors, reproduce bias, or become tools of disinformation. Materials and technologies may depend on fragile supply chains. Space systems can become strategically sensitive. Industrial processes can be vulnerable to cyber disruption. Strategy AV21's technological programmes therefore intersected with national resilience. Research on technologies in the public interest must include reliability, robustness, transparency, safety, and social trust. Otherwise, innovation can create new vulnerabilities at the same time as it solves old problems.

This security dimension was closely connected with the question of sovereignty. For small and medium-sized countries, technological sovereignty does not mean complete self-sufficiency. It means having enough knowledge, expertise, infrastructure, and international networks to make informed choices, participate in high-level collaborations, avoid total dependence, and protect critical capacities. The Czech Academy cannot by itself guarantee technological sovereignty, but it can contribute to it by maintaining advanced research communities. Strategy AV21 made this contribution visible. It showed that public research is part of the strategic capacity of the state and society.

The relationship between the Academy and industry was especially important in this field. Strategy AV21's public-interest orientation did not reject cooperation with business. On the contrary, technologies, materials, diagnostics, AI, and energy systems all require contact with application sectors. However, the Academy's cooperation with industry had to be based on scientific strength and long-term value, not only on immediate commercial demand. The programme format helped organise such cooperation by creating thematic platforms through which companies could recognise relevant Academy expertise. This strengthened the Academy's role as an increasingly important economic factor while preserving its identity as a research institution (*Czech Academy of Sciences, 2017*).

The application laboratories associated with the Strategy AV21 vision were part of this broader effort to deepen contact with the application sphere. They represented an attempt to make the Academy's research capacities more accessible for practical use without reducing the Academy to an applied service organisation. This distinction was important. The public-

interest value of technology transfer depends on the depth of the underlying research and on the ability to maintain long-term scientific independence. Strategy AV21 therefore treated application not as the opposite of basic research, but as one of the pathways through which basic research enters social and economic life.

The Academy's technological programmes also contributed to education and human capital, even though AV ČR is not primarily a teaching institution. Future industries require experts who can work across disciplines, understand advanced instruments, analyse data, communicate with industry, and think ethically about innovation. Strategy AV21 programmes created environments in which early-career researchers could participate in interdisciplinary and application-oriented work. They also supported public communication, workshops, cooperation with universities, and links with doctoral education. In this way, the technological cluster contributed to the formation of a new scientific generation prepared for a more complex innovation system.

The innovation model implied by Strategy AV21 was therefore richer than linear transfer from laboratory to market. It resembled an ecosystem model in which basic research, applied development, public policy, industry, education, social trust, and international cooperation interact. Discoveries may move towards applications, but practical problems may also generate new basic questions. Industrial cooperation may reveal material constraints, while social analysis may reveal adoption barriers. AI may transform scientific method, while scientific method may help make AI more reliable. Strategy AV21's programme-based organisation was well suited to this non-linear innovation ecology (*Mazzucato, 2018*).

This non-linear view also protected the Academy from technological determinism. Technologies do not shape society automatically. They are developed, regulated, adopted, resisted, modified, and interpreted by people and institutions. Digitalisation can strengthen democracy or weaken it, depending on governance and communication. AI can support medicine or spread misinformation. Materials can enable sustainability or deepen resource dependence. Industrial automation can improve productivity or produce exclusion. Strategy AV21's public-interest framework allowed the Academy to ask not only what technologies can do, but under what conditions they should be developed and used.

Ethics therefore belonged inside the technological agenda, not outside it. AI, gene technologies, sensors, surveillance systems, data infrastructures, automation, and advanced materials all raise questions about human dignity, rights, transparency, responsibility, environmental consequences, and unequal access. The Academy's social sciences and humanities were needed to articulate these questions, while natural and technical sciences were needed to understand the technologies themselves. Strategy AV21's interdisciplinary structure made such ethical integration possible. It helped prevent a division in which technologists innovate first and ethicists criticise later. In the stronger model, ethical reflection participates from the beginning in defining responsible innovation.

The Czech Academy's engagement with technologies and future industries also strengthened its public visibility. Citizens may not understand the details of quantum sensing, photonics, composite materials, AI models, or plasma physics, but they encounter the consequences of technological change in work, communication, medicine, energy, transport, and public services. Strategy AV21 made it easier to explain why high-level research in these areas matters. It connected specialised research with recognisable public themes: safer diagnostics, cleaner energy, smarter industry, trustworthy AI, better materials, digital services,

and technological resilience. This communicative function was a central part of the strategy's success.

At the same time, the Academy had to avoid exaggeration. Future-oriented technological programmes are vulnerable to hype. AI, quantum technologies, advanced materials, and digital transformation often attract inflated promises. A public research institution must remain more careful. Its task is to investigate possibilities rigorously, identify limitations, and resist the pressure to turn every emerging field into a miracle solution. Strategy AV21's emphasis on top research helped maintain this discipline. Public interest is not served by technological optimism alone; it is served by reliable knowledge about what technologies can and cannot achieve.

The technological cluster therefore revealed a mature form of academic modernisation. The Academy did not become a corporate innovation centre, but neither did it remain distant from the technological forces shaping society. It entered the field as an institution capable of connecting basic science, advanced instrumentation, digital methods, materials research, industry, public policy, ethics, and communication. This was a demanding role because it required the Academy to speak several languages at once: the language of scientific excellence, the language of industrial relevance, the language of public responsibility, and the language of democratic caution. Strategy AV21 provided the organisational format for this multilingual institutional performance.

Thus, the Strategy AV21 programmes connected with technologies, digitalisation, materials, and future industries demonstrated how the Czech Academy of Sciences redefined innovation as a public-interest mission grounded in fundamental research. These programmes showed that artificial intelligence, sensing, quantum technologies, photonics, diagnostics, advanced materials, space research, nuclear systems, digital infrastructures, and future industrial processes are not isolated technical fields, but elements of a broader transformation of society. The Academy's role was to generate deep knowledge, connect disciplines, support responsible application, cooperate with industry and public institutions, and help society understand the risks and possibilities of technological change. Strategy AV21 therefore placed AV ČR at the intersection of science and future-making. It allowed the Academy to remain faithful to its classical research identity while becoming an active contributor to the technological capacity, resilience, and strategic imagination of the Czech Republic.

4. Culture, Memory, Heritage, and Human Identity

Culture, memory, heritage, and human identity formed one of the most important and intellectually distinctive thematic blocks of Strategy AV21 because they demonstrated that the Academy's public-interest mission could not be reduced to technology, health, energy, or environmental sustainability alone. A society is not sustained only by infrastructures, laboratories, industries, and medical systems. It is also sustained by language, memory, symbolic continuity, historical understanding, artistic forms, ethical reflection, collective narratives, and the ability to interpret its own experience. The Czech Academy of Sciences had inherited a particularly strong responsibility in this field because Czech scholarly institutions had long been connected with the formation of national culture, the codification of language, the interpretation of history, and the preservation of cultural memory. Strategy AV21 did not treat this inheritance as a museum-like residue of the past. It reinterpreted culture, memory,

and identity as contemporary challenges in their own right. In this sense, the humanities within Strategy AV21 were not peripheral to the Academy's modernisation; they were one of the forms through which modernisation acquired historical depth and civic meaning (*Czech Academy of Sciences, 2017*).

The placement of memory and identity within Strategy AV21 was particularly significant because contemporary European societies are increasingly shaped by conflicts over the past. Public debates about democracy, nationhood, socialism, occupation, war, migration, European integration, religion, minorities, gender, and geopolitical belonging are often debates about memory before they are debates about policy. Historical experience becomes politically active when groups use the past to legitimise claims, express grievance, construct identity, or resist change. The Academy's institutes dealing with history, philosophy, archaeology, philology, literature, art history, ethnology, sociology, political science, and archives therefore had a clear public role. They could help society distinguish between memory and myth, evidence and manipulation, interpretation and propaganda. Strategy AV21 gave this role an institutional and strategic frame.

The programme Memory in the Digital Age expressed one of the most visible forms of this transformation. Memory had always depended on material carriers: manuscripts, books, monuments, photographs, archives, museums, libraries, oral testimonies, landscapes, and rituals. The digital age changed the conditions under which memory is produced, stored, accessed, circulated, and contested. Digitisation opened archives and collections to wider audiences, but it also created new problems of selection, authenticity, long-term preservation, metadata, interpretation, algorithmic visibility, and digital inequality. Strategy AV21 recognised that the digital transformation of memory was not only a technical matter. It was a cultural and institutional challenge requiring cooperation between humanities scholars, archivists, librarians, information specialists, computer scientists, conservators, and public communicators (*Czech Academy of Sciences, n.d.*).

Digital humanities played a central role in this context. The creation of shared digital environments, portals, databases, and access points for social-science and humanities resources helped make dispersed scholarly materials more visible and usable. Such work may appear less dramatic than laboratory discovery, but it changes the infrastructure of knowledge. A digitised correspondence network, historical database, manuscript collection, linguistic corpus, or archaeological record can transform the questions researchers ask and the ways the public encounters the past. Strategy AV21 helped legitimise this infrastructural labour as public-interest research. It showed that the preservation and accessibility of sources are not secondary technical services, but conditions for historical understanding and democratic cultural life (*Czech Academy of Sciences, n.d.*).

The digital turn also raised new questions about collective memory itself. Online platforms create rapid cycles of remembrance, forgetting, commemoration, outrage, and reinterpretation. Historical events can reappear suddenly through anniversaries, political conflicts, viral images, or social-media disputes. Digital traces can be studied quantitatively, but they also require critical interpretation because attention is not the same as understanding. Strategy AV21's attention to memory in the digital age therefore connected Czech humanities with broader international discussions about how digital media transform remembrance. The Academy could contribute both through traditional source criticism and through new digital methods. This combination was crucial because the digital age did not

abolish the historian's craft; it expanded and complicated it (*Yasseri, Gildersleve, & David, 2022*).

Cultural heritage became another field in which Strategy AV21 linked historical knowledge with modern technologies. Heritage is often understood as preservation of monuments, objects, texts, buildings, traditions, or landscapes. Yet in contemporary society, heritage also involves scientific analysis, conservation technologies, digital documentation, legal protection, tourism, education, identity politics, and public debate. The Academy's archaeological, art-historical, historical, architectural, chemical, physical, and material-science expertise could therefore converge around heritage as a public-interest field. Strategy AV21 made this convergence easier by allowing projects on historical correspondence, monuments, material culture, archaeological documentation, and digital presentation to appear within a common strategic horizon. Heritage was no longer only about saving the past; it was about making the past intelligible, accessible, and responsibly present.

The programme The Power of Objects: Materiality between Past and Future deepened this line of thought by placing materiality itself at the centre of research. Objects are not passive remnants of human activity. They organise perception, transmit memory, structure social relations, embody power, and connect technologies, economies, rituals, and identities. A coin, manuscript, machine, textile, monument, religious object, tool, archive box, sculpture, scientific instrument, or everyday artefact can reveal relations between material form and social meaning. Strategy AV21's materiality programme aimed to bring together researchers from all three scientific areas of the Academy and from other academic and public institutions. This was highly characteristic of the strategy's logic: material culture became a meeting point for archaeology, history, anthropology, art history, philosophy, conservation science, chemistry, physics, and social theory (*Czech Academy of Sciences, n.d.*).

The focus on materiality also challenged the idea that humanities research is concerned only with texts and ideas. Material objects carry knowledge in ways that cannot be reduced to written records. They preserve traces of technique, trade, labour, bodily practice, social hierarchy, religious life, political authority, and aesthetic value. Scientific methods can identify composition, provenance, age, degradation, pigment, fibre, residue, or manufacturing technique. Humanistic interpretation can explain meaning, use, circulation, symbolism, and historical context. Strategy AV21 enabled these approaches to meet. It showed that cultural heritage is one of the fields where the natural sciences and humanities can cooperate most organically.

The integration of memory and materiality was especially important for understanding Czech and Central European history. The region has been shaped by changing borders, multilingual communities, confessional conflicts, Habsburg rule, national movements, democratic statehood, occupation, expulsion, communism, normalisation, dissent, revolution, and European integration. These transformations left traces in architecture, cemeteries, archives, museums, public monuments, private objects, industrial sites, and urban landscapes. Heritage in such a context is never politically neutral. It raises questions about whose memory is preserved, whose suffering is recognised, whose language appears in public space, and how historical complexity is represented. Strategy AV21 allowed the Academy to address these questions as scholarly and civic problems at the same time.

The programme Anatomy of European Society, History, Tradition, Culture, Identity placed Czech questions within a wider European frame. Europe is not only a political and economic

union; it is also a historical and cultural space made from shared inheritances, conflicts, translations, borders, religions, ideologies, institutions, and memories. The Czech lands have always belonged to this European space in a complex way: geographically central, linguistically and culturally plural, historically connected to both Western and Central European traditions, and repeatedly affected by imperial, national, and ideological projects. Strategy AV21 used the study of European society and identity to show that Czech scholarship could contribute to debates about Europe not as an external object, but from within its historical fabric (*Czech Academy of Sciences, n.d.*).

This European orientation mattered especially after the post-1989 transformation. The Czech Republic's return to Europe was never only a matter of accession to institutions such as the European Union or NATO. It was also a reinterpretation of historical belonging after decades of socialist isolation and ideological distortion. Academic research played an important role in this reinterpretation by studying statehood, democracy, law, religion, culture, political thought, migration, minorities, and transnational connections. Strategy AV21 placed such research in the public-interest framework because European identity was not a settled fact. It remained a question to be historically examined, critically discussed, and culturally negotiated.

The programme Identities in the World of Wars and Crises brought this issue into the present more sharply. Identity becomes especially visible in moments of crisis because people and communities ask who they are, whom they trust, where they belong, and what values they defend. Wars, forced migration, geopolitical instability, economic insecurity, pandemics, climate anxiety, and information conflicts all transform identity debates. In the Czech and European context, Russia's war against Ukraine, the crisis of liberal democracy, polarisation, and global power shifts intensified questions of national, European, regional, religious, linguistic, and political identity. Strategy AV21's identity programme responded to this destabilised environment through interdisciplinary and comparative research. It recognised that identity is not a static possession, but a dynamic process shaped by conflict, memory, institutions, language, and imagination (*Czech Academy of Sciences, n.d.*).

Human identity, in this framework, is not merely a psychological or philosophical abstraction. It is formed through social practices, narratives, bodies, places, objects, media, rituals, education, law, and historical experience. A person understands themselves partly through family memory, national history, language, religion, profession, gender, region, class, political community, and digital environment. Collective identities are similarly layered and contested. Strategy AV21's contribution was to place identity among the major public challenges of the 21st century, alongside energy, health, sustainability, and technology. This was important because identity conflicts can destabilise societies as powerfully as material crises. They influence elections, policy acceptance, migration debates, security perceptions, and trust in institutions.

The humanities were indispensable in this field because they study meaning. Meaning is not an ornament attached to social life after economic, biological, or technological processes have done their work. It shapes action from the beginning. People accept or reject vaccines, climate policies, European integration, migration, heritage protection, digital technologies, and social reforms partly according to the meanings they attach to them. Historical analogies, moral vocabularies, national myths, religious symbols, literary forms, and media narratives all influence behaviour. Strategy AV21 therefore treated cultural and humanistic knowledge as

part of society's capacity for self-understanding. This was a strong answer to narrow definitions of public usefulness.

Social sciences connected these humanistic questions with empirical analysis of contemporary society. Sociology, political science, economics, law, psychology, demography, and communication studies could examine how identities are distributed, mobilised, institutionalised, and transformed. They could analyse public opinion, media systems, inequality, migration, radicalisation, trust, education, civic participation, and policy effects. When combined with historical and philosophical work, social-science research made identity and memory both empirically grounded and interpretatively rich. Strategy AV21's programme-based format encouraged precisely this combination. It avoided the separation between cultural interpretation and social diagnosis.

Language occupied a special place in this cultural block because Czech scientific and cultural history has long been connected with linguistic identity. The national revival, philology, literary studies, lexicography, language culture, and education all treated language as a carrier of collective existence. In the digital age, language again became a strategic object, but in new forms: corpora, machine translation, language technologies, digital communication, media discourse, minority languages, and online misinformation. Strategy AV21's communication and digital-memory orientations allowed linguistic research to remain central to public-interest science. Language is not only a medium of communication; it is a field where power, identity, memory, and technology intersect.

Communication itself linked culture and society in a particularly direct way. Programmes dealing with forms and functions of communication, memory, identity, and digitalisation showed that the public sphere depends on more than the availability of information. It depends on interpretative competence, trust, narrative frames, media infrastructures, and the ability to distinguish argument from manipulation. In a period of disinformation and polarisation, communication research became part of civic security. The Academy's humanities and social sciences could help society understand how meanings circulate, how propaganda works, how expertise is challenged, and how public debate can be damaged or repaired. Strategy AV21 thus placed communication within the same public-interest horizon as health or energy.

The Academy's archival and library institutions were also central to this mission. Archives and libraries are not passive storehouses. They are active infrastructures of scholarly and public memory. They decide how sources are preserved, catalogued, digitised, contextualised, and made accessible. The digital humanities initiatives connected with Strategy AV21 revealed the importance of such work. A society without accessible archives becomes vulnerable to myth, forgetting, and manipulation. A society with well-preserved and critically interpreted sources can debate its past with greater responsibility. Strategy AV21 therefore strengthened the Academy's role as a guardian and interpreter of evidence.

The cultural heritage field also showed how public interest may require patience rather than immediacy. The restoration of a manuscript, the cataloguing of correspondence, the analysis of a monument, the preparation of a critical edition, or the digitisation of an archive may take years. Such work does not always produce rapid headlines. Yet it creates durable cultural value. It allows future researchers, teachers, citizens, artists, and institutions to access knowledge that would otherwise be lost or inaccessible. Strategy AV21's inclusion of such work demonstrated a long-term understanding of public benefit. Not all socially valuable research solves an urgent crisis; some of it preserves the conditions for future understanding.

This long-term logic was especially relevant for memory of the 20th century. The history of occupation, the Holocaust, communist rule, political repression, dissent, exile, normalisation, and the Velvet Revolution remains central to Czech democratic self-understanding. As witnesses pass away, archives, oral histories, scholarly interpretation, public exhibitions, education, and digital resources become even more important. Strategy AV21's memory-oriented programmes could support this transition from living memory to documented and interpreted memory. The Academy's responsibility was not to dictate a single official interpretation, but to provide evidence, context, and critical scholarship. This is a democratic rather than ideological form of memory work.

At the same time, the humanities must avoid becoming servants of national self-congratulation. Critical historical research often complicates comfortable narratives. It reveals ambiguity, exclusion, violence, collaboration, forgetting, and conflict. Strategy AV21's public-interest frame should therefore not be understood as a demand that culture and memory research produce positive identity stories. Public interest may be served by uncomfortable knowledge. A mature society needs scholarship capable of examining its own myths, failures, and contradictions. The Academy's autonomy is essential here because memory research becomes dangerous when subordinated to political convenience.

The study of heritage also raised questions of ownership and participation. Cultural objects and historical narratives often belong simultaneously to local communities, national institutions, minority groups, religious communities, professional experts, and international audiences. Decisions about preservation, interpretation, or display can therefore be contested. Strategy AV21's interdisciplinary and public-facing orientation allowed heritage to be studied not only as expert conservation, but also as a social relationship. This is particularly important in Central Europe, where Jewish, German, Roma, Czech, Slovak, Austrian, Polish, Hungarian, and other histories intersect in material and symbolic space. Heritage research can make such plurality visible rather than allowing national narratives to flatten it.

The connection between culture and technology was another defining element of this block. Digitisation, imaging, 3D documentation, databases, AI-assisted text analysis, geographic information systems, virtual exhibitions, and online educational platforms all changed the study and presentation of heritage. Strategy AV21 allowed the Academy to connect humanities scholarship with technical innovation. This was not only a matter of making old materials available online. It changed research questions themselves. Scholars could trace networks, compare large textual corpora, reconstruct landscapes, visualise correspondence, analyse image collections, and connect dispersed sources across institutions. Digital tools therefore became instruments of cultural analysis, not merely instruments of dissemination.

However, digital heritage also brought risks. Digital access can create the illusion that a source is self-explanatory once it is online. Algorithms can privilege certain materials while hiding others. Digital formats can become obsolete. Metadata choices can shape interpretation. Commercial platforms can influence public memory. Strategy AV21's scholarly framing was important because it insisted that digitisation must be accompanied by critical method. The public interest is not served by access alone; it is served by meaningful, contextualised, sustainable, and ethically responsible access. This is a central principle of digital humanities as a public mission.

The programme on materiality between past and future also invited reflection on the relationship between objects and power. Objects can stabilise hierarchies: crowns, uniforms,

weapons, religious artefacts, legal documents, museum displays, state symbols, architectural forms, and technological devices can all organise social imagination. At the same time, objects can move, be reused, reinterpreted, stolen, restored, displayed, or contested. Their meanings change across contexts. Strategy AV21's attention to materiality therefore connected cultural history with political anthropology, sociology, philosophy, conservation science, and technological studies. It showed that objects are active participants in the making of social worlds.

Human identity in the world of wars and crises also required attention to trauma and displacement. Wars and crises force people to leave homes, change languages, reinterpret loyalties, and rebuild communities. They also force host societies to define solidarity, belonging, and limits of responsibility. The Czech Republic's response to Ukrainian refugees after 2022, as well as its older memories of exile, occupation, and migration, made such questions highly relevant. Strategy AV21's identity programme provided a framework for studying these processes comparatively and historically. It showed that identity research can contribute to public understanding during geopolitical crisis.

Culture and memory also intersected with education. Schools transmit historical narratives, literary canons, civic values, and cultural references. They also become sites where societies debate what should be remembered and how. The Academy's research in history, literature, language, philosophy, sociology, and education can inform textbooks, exhibitions, public lectures, teacher training, and educational resources. Strategy AV21's public-interest orientation made this educational function more visible. A national academy does not educate only through formal teaching; it educates by shaping the quality of public knowledge available to society.

The cultural block of Strategy AV21 also contributed to international visibility. Czech humanities and social sciences could enter European and global conversations about memory studies, heritage preservation, digital humanities, identity, material culture, communication, and crisis. These fields are not provincial. They address questions shared by many societies, even when grounded in local materials. Strategy AV21 allowed Czech research to present its specific historical experience as part of broader comparative scholarship. This strengthened the Academy's role as both a national and international intellectual institution.

The integration of culture, memory, heritage, and identity also helped correct a common misunderstanding of modernisation. Modernisation is often associated with technology, management, economic growth, or institutional efficiency. Strategy AV21 showed that modernisation also requires the renewal of cultural self-understanding. A society that innovates technologically but loses the capacity to interpret its history may become vulnerable to manipulation, cynicism, or identity panic. A society that preserves heritage without adapting to digital and social change may turn memory into nostalgia. The Academy's cultural programmes therefore contributed to a more balanced form of modernisation: one that connects future-oriented research with historical consciousness.

This balance was especially important for the modern image of AV ČR. The Academy could present itself not only as a producer of scientific and technological knowledge, but also as an institution responsible for the intellectual continuity of Czech society. In the public imagination, academies often carry an aura of tradition. Strategy AV21 did not reject this aura, but it gave it active content. Tradition became not a static claim to prestige, but a resource for addressing contemporary crises of memory, identity, communication, and cultural orientation.

The Academy thus appeared as both old and modern: rooted in learned culture, but capable of responding to the digital and geopolitical conditions of the present.

The cultural and identity programmes also deepened the ethical meaning of "public interest". Public interest is not only the interest in living longer, producing more energy, developing better technologies, or protecting ecosystems. It is also the interest in truthful memory, open interpretation, cultural plurality, language, dignity, identity, and the capacity to live with historical complexity. These are less measurable than patents or energy outputs, but they are no less important for democratic society. Strategy AV21's inclusion of these themes therefore broadened the very definition of what a public-interest research institution should be.

Thus, the Strategy AV21 programmes connected with culture, memory, heritage, and human identity revealed the Czech Academy of Sciences as an institution concerned not only with the material and technological future of society, but also with its historical consciousness, symbolic order, and interpretative capacity. They showed that memory in the digital age, European society, materiality, cultural heritage, communication, and identities in wars and crises are not marginal humanities topics, but central public-interest challenges. These programmes connected archives with digital technologies, objects with power, heritage with science, identity with geopolitical crisis, and historical interpretation with democratic resilience. Strategy AV21 thereby gave the humanities and social sciences a strategic place within the modern Academy. It affirmed that a society capable of innovation must also be capable of memory, self-criticism, cultural continuity, and responsible interpretation of its own past and present.

Strategy AV21 and the Modern Image of the Academy

1. Public Communication and Visibility of Science

Public communication became one of the most important dimensions of Strategy AV21 because the strategy was designed not only to reorganise research, but also to change the way the Czech Academy of Sciences appeared in public life. The Academy could no longer rely on the assumption that society would automatically understand why specialised research institutes matter. A modern public research institution must show how its work relates to the lives, risks, memories, technologies, landscapes, health, and future choices of citizens. Strategy AV21 therefore created a new language of visibility. It allowed the Academy to present research not as a scattered collection of institute outputs, but as a coordinated response to major public-interest problems. This was a major shift in the Academy's public image. Visibility became not an optional supplement to research, but part of the institutional meaning of research itself (*Czech Academy of Sciences, 2017*).

The motto "Top research in the public interest" already contained a communicative ambition. It was short enough to be publicly recognisable, but broad enough to include the Academy's full disciplinary range. It told citizens, policymakers, journalists, teachers, students, and partners that the Academy's work was both scientifically serious and socially relevant. The phrase also helped the Academy avoid two weaker forms of public presentation. It did not

reduce science to entertainment or immediate usefulness, but it also did not hide behind the language of specialised excellence alone. It connected excellence with responsibility. In this sense, Strategy AV21 functioned as a bridge between internal scientific quality and external public intelligibility.

Public communication was especially necessary because the Academy's institutional structure is difficult for non-specialists to understand. AV ČR consists of many institutes with different names, disciplines, histories, locations, and research cultures. For an ordinary citizen, this structure may appear remote or opaque. Strategy AV21 simplified the public map of the Academy without simplifying the research itself. Instead of asking the public to understand every institute separately, it organised communication around themes such as energy, health, biodiversity, artificial intelligence, infectious diseases, memory, society, materials, and sustainability. These themes are closer to the public's experience of contemporary life. They make the Academy visible through problems that citizens can recognise.

This does not mean that Strategy AV21 turned science into public relations. A serious academy cannot communicate by replacing knowledge with slogans. Its credibility depends on the fact that public narratives are anchored in genuine research capacities, peer-reviewed work, long-term expertise, and institutional depth. Public communication under Strategy AV21 therefore had to maintain a difficult balance. It needed to be clear without being simplistic, engaging without being sensationalist, and publicly relevant without becoming politically subordinate. The Academy's task was not to market itself as a brand detached from substance. It was to explain why its research substance matters.

The need for such communication reflected a wider transformation in the relationship between science and society. During much of the 20th century, scientific authority often rested on distance: scientists produced knowledge, and the public was expected to trust experts. By the late 20th and early 21st centuries, this model had become insufficient. Scholars of science communication increasingly emphasised dialogue, public engagement, participation, trust, and the social contexts in which knowledge is received (*Burns, O'Connor, & Stocklmayer, 2003*; *Bucchi & Trench, 2014*; *Stilgoe, Lock, & Wilsdon, 2014*). Strategy AV21 should be understood within this broader shift. It made the Academy's public role more dialogic, more thematic, and more visibly connected with societal concerns.

The Academy's history gave this communicative turn particular significance. Czech science had long possessed a public dimension, especially during periods when scholarship was connected with language, culture, national identity, and modernisation. Under socialism, however, public communication of science was often entangled with ideological presentation, state planning, and official optimism. After 1989, the Academy had to restore scientific autonomy and credibility, which naturally encouraged a return to international standards and disciplinary seriousness. Strategy AV21 represented a later phase in which public communication could be rebuilt on democratic foundations. It did not ask science to serve propaganda; it asked science to speak responsibly to society.

This distinction is crucial. Public communication in a democratic academy is not the same as state-directed popularisation. It is not a one-way transmission of approved conclusions. It is a process through which researchers explain methods, uncertainty, evidence, limitations, and relevance. It also requires awareness that citizens may have legitimate concerns, local knowledge, ethical questions, and distrust shaped by past experience. Strategy AV21

strengthened this democratic model by framing the Academy's communication around public-interest programmes rather than institutional self-praise. The public could see not only that the Academy existed, but what kinds of problems it was trying to understand.

The public events organised by the Academy formed one important part of this visibility. The Week of the Czech Academy of Sciences, Science Fair, Brain Awareness Week, exhibitions, lectures, workshops, workplace visits, science cafés, documentaries, and laboratory open days all helped bring research into public space. Such events matter because science is often invisible in ordinary life. Laboratories, archives, observatories, field stations, and computational centres are usually closed spaces, not because they are secret, but because they require specialised work. Public events temporarily open these spaces symbolically and sometimes physically. They allow citizens to encounter research as a living activity performed by real people.

The Week of the Czech Academy of Sciences had special institutional meaning in this regard. It continued and transformed earlier traditions of science festivals and became a large public celebration of the Academy's work across disciplines. Its structure, with lectures, exhibitions, workplace events, documentaries, workshops, science cafés, and activities throughout the country, corresponded well to the Strategy AV21 idea of research in the public interest. It did not present one discipline as the face of science. It showed science in all its variety, from laboratories to humanities, from young visitors to adult audiences, from Prague to regional centres. This helped communicate the Academy as a national institution rather than a closed metropolitan elite (*Czech Academy of Sciences, n.d.*).

The regional dimension of public communication was particularly important. A national academy must not appear as an institution located only in Prague and speaking only to policymakers or university audiences. Many Strategy AV21 themes are deeply regional: drought, forests, biodiversity, local heritage, industrial transformation, public health, energy infrastructure, ageing communities, and regional inequalities. Public events held in different cities and connected with individual institutes allowed the Academy to be visible beyond the capital. This strengthened its role as a national knowledge institution. It also helped citizens see that research is relevant to places where they live, not only to abstract national policy.

Science fairs and open days also contributed to the visibility of scientific practice. Public communication is strongest when it does not merely report results, but shows how knowledge is made. A child looking through a microscope, a student entering a laboratory, a visitor seeing experimental instruments, or an audience discussing a historical source can experience science as process rather than as authority. This experience matters for trust. People are more likely to understand the value of research when they see its methods, patience, uncertainty, and human labour. Strategy AV21's public-interest orientation gained credibility when connected with such direct encounters.

Student internships and educational initiatives strengthened this connection further. The Academy is not a university in the ordinary sense, but it participates in education through doctoral training, university cooperation, public lectures, school programmes, internships, mentoring, and open science activities. Public communication therefore also becomes a form of scientific reproduction. It helps young people imagine themselves as future researchers, technicians, teachers, physicians, historians, environmental experts, or data scientists. Strategy AV21's thematic programmes provided attractive entry points for such imagination.

Energy, AI, health, biodiversity, memory, and space are themes that can draw students into science because they feel connected to the future.

Citizen science added another important layer to the public visibility of the Academy. In citizen science, the public is not only an audience but, in certain forms, a participant in the production or collection of knowledge. This does not abolish professional expertise, but it can expand observation, strengthen public understanding, and create a sense of shared responsibility. Environmental monitoring, biodiversity observation, language documentation, historical memory projects, and public data collection are all fields where citizens may contribute meaningfully under scientific guidance. Strategy AV21's public-interest logic was compatible with such practices because it emphasised the relationship between research and society. Citizen involvement can make science more visible, but also more socially grounded (*Irwin, 1995*).

The Academy's media communication also became more important under the Strategy AV21 framework. Press releases, expert contacts, interviews, periodicals, online articles, podcasts, video series, social media, and visual materials all help translate research into public narratives. In the digital age, silence is not neutrality. If serious research institutions do not communicate, public space may be filled by speculation, misinformation, commercial simplification, or ideological distortion. The Academy's public communication therefore has a protective function. It helps maintain the presence of evidence-based knowledge in public debate.

The Strategy AV21 website and related digital presentation tools became part of this communicative infrastructure. A programme-based strategy needs a clear digital interface because citizens, journalists, policymakers, teachers, and partners must be able to find information about programmes, coordinators, topics, outputs, and news. The Academy's recent emphasis on more intensive communication, clearer presentation of findings, and modernisation of the Strategy AV21 web environment reflected this need. A public-interest programme cannot remain hidden in internal documents. Its legitimacy grows when its activities, results, and forms of cooperation are accessible and understandable (*Czech Academy of Sciences, 2026*).

Digital communication also changes the temporality of scientific visibility. Traditional scholarly publication is slow, specialised, and cumulative. Public digital communication is faster, more fragmented, and more exposed to immediate reaction. The Academy had to learn to operate in both temporalities at once. It must protect the slow time of research while participating in the fast time of public debate. Strategy AV21 helped by giving the Academy stable thematic frames that could be used repeatedly in communication. Energy, biodiversity, infectious diseases, AI, memory, and public policy are not one-day topics; they provide durable contexts for explaining new results.

The public communication of uncertainty is one of the most difficult responsibilities of a research institution. Citizens often expect science to provide clear answers, while serious research often produces probabilities, models, scenarios, competing interpretations, or provisional conclusions. This is especially visible in climate science, pandemic response, energy policy, biodiversity loss, AI ethics, and public policy evaluation. Strategy AV21's public-interest mission required the Academy to explain uncertainty without undermining trust. The point was not to pretend that science knows everything. It was to show why scientifically disciplined uncertainty is more reliable than unsupported certainty.

The Academy's communication of health and crisis-related research made this especially clear. During public health emergencies, citizens need timely information, but they also need explanations of changing evidence. Recommendations may change because knowledge improves, not because science has failed. A research institution that communicates carefully can help society understand this process. Strategy AV21's programmes on infectious diseases, resilience, public policy, and communication created a wider context for such work. They showed that public communication is itself a component of social resilience.

The same applies to climate and environmental communication. Climate change, biodiversity loss, drought, forests, water, and sustainable food systems are complex and sometimes politically divisive issues. Public communication must make long-term processes visible without turning them into catastrophe rhetoric that paralyses action. It must explain both risks and possibilities. The Academy's environmental and sustainability programmes provided scientific substance for this communication. Strategy AV21 allowed environmental research to speak in a public language grounded in evidence, not activism alone.

Technology communication presented another challenge. Artificial intelligence, genetic technologies, nuclear energy, quantum technologies, digital platforms, and advanced materials often provoke both fascination and fear. Public communication must avoid technological hype, but also avoid unproductive alarmism. Strategy AV21's public-interest frame allowed the Academy to present technologies as objects of research, tools of innovation, sources of risk, and subjects of ethical reflection. This balanced language is important because democratic societies need technological literacy. Citizens should be able to discuss technologies not only as consumers, but as members of a public affected by them.

The humanities and social sciences played a central role in the Academy's public visibility because they are often closer to public language, memory, and identity. Research on history, culture, communication, public policy, language, society, and identity can enter public debate directly. Yet this visibility also exposes these fields to political controversy. Historical interpretation, memory of communism, national identity, migration, religion, gender, and European integration are not neutral public topics. Strategy AV21 gave humanities and social sciences a strategic framework that protected their public role as research-based, not merely opinion-based. It helped show that culture and memory require evidence, method, and scholarly responsibility.

Public communication also changed the relationship between the Academy and journalism. Journalists need reliable experts, clear explanations, and access to research findings. Scientists need journalists capable of presenting complexity without distortion. The Academy's media infrastructure, expert databases, press releases, and public-facing articles all contributed to this relationship. Strategy AV21 strengthened it by making research themes easier to identify. A journalist working on energy, infectious disease, biodiversity, AI, public policy, or memory could more easily recognise the Academy as a source of expertise.

This visibility had implications for political legitimacy as well. Publicly funded research institutions must explain themselves to taxpayers, government, parliament, ministries, and civic society. Strategy AV21 made the Academy's contribution more visible by connecting research with public problems and by presenting outputs in an organised way. However, visibility must not become dependence on political approval. The Academy's credibility depends on its capacity to speak independently, including when its findings are inconvenient. Public communication under Strategy AV21 therefore had to support autonomy, not replace it.

The Academy's public voice is valuable because it is grounded in research rather than political convenience.

The public communication of Strategy AV21 also contributed to the Academy's identity as a whole. Institutes often communicate their own achievements, but the Academy needed a shared public narrative. Strategy AV21 provided that narrative. It allowed the Academy to say: these different institutes, disciplines, and programmes belong to one institution because they contribute together to the public interest. This was essential for institutional coherence. A decentralised academy becomes publicly stronger when it can present diversity as organised capacity rather than as fragmentation.

The visual dimension of scientific communication also became more important. Images from laboratories, fieldwork, microscopy, space observation, historical collections, environmental research, and scientific instruments can make research emotionally and intellectually accessible. Contests, exhibitions, videos, and online galleries can reveal the aesthetic dimension of science without trivialising it. The Academy's public communication increasingly used such visual formats to show that science is not only equations, articles, and reports, but also observation, craft, material practice, and wonder. Strategy AV21's public-interest orientation gave such visibility a deeper purpose. Images were not only attractive; they helped citizens encounter the world of research.

At the same time, communication must avoid the danger of reducing science to spectacle. Popularisation can become superficial if it values surprise more than understanding. A serious academy must use attractive formats while preserving intellectual content. This is especially important when communicating difficult topics such as infectious diseases, nuclear energy, biodiversity loss, identity conflicts, or AI risks. Strategy AV21's strength was that its public communication could draw on substantial programmes rather than isolated events. The public-facing message had research depth behind it.

The Academy's public visibility also benefited from the fact that Strategy AV21 connected research with practical outputs and policy relevance. Policy briefs, public debates, expert platforms, cooperation with public administration, and Science4Policy-type activities made research visible to decision-makers as well as citizens. This widened the audience of communication. Public communication does not mean only communication with the general public. It also includes communication with policymakers, teachers, municipalities, hospitals, companies, cultural institutions, and professional communities. Strategy AV21's programme architecture made such differentiated communication possible (*Czech Academy of Sciences, 2026*).

The relation between communication and knowledge transfer was therefore close. Knowledge transfer is often associated with technology transfer, patents, licensing, or industrial cooperation. Strategy AV21 broadened the meaning of transfer. Knowledge can be transferred through policy advice, public explanation, educational resources, databases, exhibitions, citizen-science tools, expert consultations, media work, and cultural interpretation. Public communication is one of the forms through which scientific knowledge enters society. It does not replace technology transfer, but it complements and expands it.

Public communication also has an international dimension. The Academy presents Czech research to foreign partners, European institutions, international scholars, and global audiences. English-language websites, reports, press materials, and international events help AV ČR appear as a modern European research institution. Strategy AV21's themes are

internationally recognisable: AI, biodiversity, infectious diseases, sustainability, energy, memory, identity, and public policy. This makes the Academy's work more visible beyond national borders. The strategy therefore supports both domestic legitimacy and international reputation.

The Academy's communication practices also reflect the changing expectations of openness in science. Open access, open data, public engagement, research integrity, and transparency have become central concerns in contemporary research culture. Public visibility is not only about explaining results after publication. It is also about making research processes, infrastructures, collaborations, and responsibilities more transparent where possible. Strategy AV21 contributed to this culture by presenting programmes, coordinators, aims, and outputs in a public form. It made the Academy's strategic priorities more visible and therefore more open to public understanding.

There is, however, a tension between visibility and the slow, specialised nature of research. Not every valuable scientific activity can be easily communicated. Some work is technical, preliminary, negative, incremental, or intelligible only after long preparation. An academy must protect such work from the demand for constant public performance. Strategy AV21 did not solve this tension completely, but it offered a reasonable compromise. It created thematic frames through which specialised work could become visible at the appropriate level of generality, without forcing every result into immediate public language.

The public communication function of Strategy AV21 also helped strengthen trust in the Academy as an institution. Trust is not built only by claiming authority. It is built through repeated, credible, transparent, and useful encounters. When citizens see scientists explaining drought, pandemics, AI, heritage, memory, health, or biodiversity in a responsible way, the institution becomes more familiar. Familiarity does not guarantee agreement, but it reduces distance. Strategy AV21 made such encounters more systematic by linking communication to programmes rather than leaving it to isolated individual enthusiasm.

This is especially important in a period when expert institutions face suspicion, misinformation, and political polarisation. Science is sometimes portrayed as elitist, detached, ideological, or hostile to ordinary experience. A public-interest academy must answer not by abandoning expertise, but by making expertise more accountable and understandable. Strategy AV21 helped the Academy show that researchers are not separate from society; they work on problems that affect society. At the same time, it showed that social relevance does not require the sacrifice of scientific standards. This dual message was central to the Academy's modern visibility.

The public image of the Academy therefore changed from that of a mainly internal research corporation to that of an institution visibly engaged with national and global challenges. This did not mean that the Academy became less scholarly. It meant that scholarship acquired a clearer public face. Strategy AV21 enabled citizens to recognise AV ČR through the problems it addressed, the programmes it organised, and the events and communication channels through which it presented its work. Public communication became a form of institutional self-definition. The Academy was not only producing knowledge; it was showing why knowledge matters.

Thus, public communication and the visibility of science became essential to Strategy AV21 because the Academy's public-interest mission could not remain hidden inside institutes, reports, laboratories, archives, and specialist journals. Strategy AV21 gave AV ČR a

communicative architecture: thematic programmes, public events, digital platforms, media channels, educational activities, visual formats, citizen engagement, and policy-oriented outputs. Through this architecture, the Academy made its research more intelligible to citizens, more accessible to policymakers, more attractive to students, and more recognisable internationally. The strategy did not reduce science to popularisation; it connected communication with excellence, responsibility, autonomy, and public trust. In doing so, it helped transform the Czech Academy of Sciences into a more visible national knowledge institution capable of speaking to society while remaining faithful to the depth and seriousness of academic research.

2. Expertise for State, Society, and Citizens

Expertise became one of the central forms through which Strategy AV21 reshaped the modern public role of the Czech Academy of Sciences. The Academy had always possessed expert capacity, because its institutes concentrated specialised knowledge, long-term data, archives, laboratories, collections, instruments, and professional communities. Yet Strategy AV21 made this expert capacity more visible, more coordinated, and more explicitly connected with public-interest problems. Expertise was no longer only something offered occasionally when a ministry, court, school, museum, hospital, company, or journalist requested it. It became part of the Academy's strategic self-understanding. The Academy presented itself as an institution able to help the state, society, and citizens understand complex issues that cannot be solved through political will, administrative routine, or public opinion alone. In this sense, Strategy AV21 transformed expertise from a dispersed institutional asset into one of the defining features of the Academy's civic mission (*Czech Academy of Sciences, 2017*).

The phrase "expertise for the state" must be understood carefully. It does not mean that the Academy became an instrument of the government or a technical department of public administration. The history of the Czechoslovak Academy under socialism had shown the danger of subordinating scientific knowledge to political command. After 1989, the Academy rebuilt its legitimacy through autonomy, international standards, evaluation, and intellectual freedom. Strategy AV21 did not reverse this post-socialist recovery. Rather, it asked how an autonomous academy could provide knowledge useful to public institutions without losing its independence. This distinction is essential: democratic expertise serves the state best when it is not captured by the state.

The state needs expertise because modern governance operates under conditions of complexity. Energy transition, infectious diseases, climate adaptation, cyber security, public health, social inequality, education, demographic ageing, biodiversity, artificial intelligence, migration, heritage protection, and economic resilience cannot be governed responsibly without knowledge. Ministries and public agencies have administrative authority, but they do not always possess the long-term scientific capacities required to understand these problems in depth. The Academy can supply evidence, scenarios, models, historical context, diagnostic tools, risk assessments, and conceptual clarification. Strategy AV21 organised such capacities into programmes that made the Academy's knowledge easier for public institutions to recognise and use. It thereby strengthened the knowledge base of the Czech state without dissolving the boundary between science and politics.

This boundary is important because expertise does not decide policy by itself. Scientific knowledge can show what is likely, what is uncertain, what risks are present, what options exist, and what consequences may follow. It cannot determine values, allocate burdens, or replace democratic decision-making. Strategy AV21 therefore positioned the Academy not as a technocratic authority above society, but as a knowledge institution that improves the quality of public reasoning. The Academy's role was to make decisions better informed, not to remove them from political accountability. This model corresponds to a mature democratic understanding of expertise, where science contributes to public judgement but does not monopolise it (*Jasanoff, 2004*; *Pielke, 2007*).

The Academy's expertise for the state was particularly visible in areas where decisions have long-term consequences. Energy policy, for example, requires knowledge about nuclear safety, renewable integration, storage technologies, materials, grid stability, emissions, geophysical risks, public acceptance, and industrial capacity. A government may decide the direction of energy policy, but the quality of that decision depends on the available knowledge. Strategy AV21's energy-related programmes gave the Academy a platform for providing such knowledge in a more integrated way. They allowed researchers from physics, chemistry, materials science, environmental research, economics, and social sciences to contribute to a field where technical, economic, environmental, and geopolitical factors interact. This is exactly the type of policy problem for which a national academy is needed.

Environmental and climate expertise provides another example. Public authorities must respond to drought, floods, forest degradation, biodiversity loss, soil erosion, water management, landscape restoration, and climate adaptation. These questions require long-term monitoring, field research, models, ecological interpretation, legal analysis, and public communication. The Academy's institutes can contribute not only individual findings, but accumulated knowledge about Czech landscapes and ecosystems. Strategy AV21 placed such knowledge in a public-interest frame and helped connect it with government, municipalities, and civic society. The result was not simply environmental advocacy, but expert capacity grounded in research.

Public health created an even more direct relation between expertise and public life. The COVID-19 pandemic showed that governments need scientific advice, but also that scientific advice must be communicated clearly, interpreted cautiously, and integrated with social realities. Virology, immunology, diagnostics, modelling, epidemiology, law, psychology, communication studies, and sociology all became relevant. The Academy's expertise was valuable because it was not limited to one dimension of the crisis. Strategy AV21's programmes on infectious diseases, resilience, public policy, and communication corresponded to the multidimensional character of health crises. They showed that expertise for the state must be interdisciplinary if the problem itself is interdisciplinary.

The Academy's expertise for society is broader than expertise for the state. Society includes schools, universities, hospitals, municipalities, businesses, cultural institutions, non-governmental organisations, professional communities, media, and citizens' groups. These actors often need knowledge but do not always access it through formal governmental channels. Strategy AV21's public-interest orientation opened the Academy more clearly to these wider social actors. It presented Academy research as a resource for many communities, not only for ministries. This was an important democratisation of expertise. Knowledge remained specialised, but its public pathways became more diverse.

For municipalities and regions, Academy expertise may be especially valuable because many contemporary problems are experienced locally. A national ministry may define a strategy, but drought affects particular landscapes, ageing affects particular communities, heritage belongs to particular places, industrial transformation affects particular regions, and public health services operate in particular local systems. The Academy's research can help local actors understand their situation within broader national and global processes. Strategy AV21's programmes on landscape, food, society, public policy, resilience, memory, and cities offered themes through which regional knowledge could be connected with national expertise. This helped overcome the distance between central scientific institutions and local public needs.

The relationship with industry and business also belongs to this wider social expertise. Companies need knowledge about materials, diagnostics, optics, biotechnology, artificial intelligence, energy systems, sensors, environmental technologies, food production, and circular economy. Strategy AV21 did not define cooperation with industry as the only or highest form of public interest, but it recognised industry as one of the places where research can become socially and economically consequential. The Academy's expertise could support innovation, testing, prototypes, methods, and strategic technological capacity. At the same time, the Academy had to preserve a distinction between public-interest expertise and private consultancy. Its cooperation with business was most legitimate when it rested on high-quality research and produced wider benefits beyond immediate commercial advantage.

Cultural institutions also relied on the Academy's expertise in distinctive ways. Museums, archives, libraries, galleries, heritage offices, schools, and media organisations often need historical, linguistic, archaeological, philosophical, ethnological, literary, and conservation knowledge. Strategy AV21's programmes on memory, materiality, European society, communication, and identity strengthened the public role of the humanities in such cooperation. Expertise in this field is not only about identifying facts. It involves interpretation, context, preservation, source criticism, and sensitivity to contested memories. The Academy thus served society not only by producing technologies or health research, but also by protecting the intellectual conditions of cultural continuity.

Expertise for citizens is perhaps the most difficult and most important dimension. Citizens rarely approach the Academy as a ministry or company would. They encounter its expertise through public lectures, media appearances, exhibitions, websites, festivals, educational materials, interviews, expert statements, popular books, podcasts, documentaries, and sometimes through direct participation in citizen science. Strategy AV21 helped make such encounters more meaningful by connecting them with recognisable themes: health, environment, food, AI, memory, energy, biodiversity, society, and security. Citizens do not need to know the full institutional structure of AV ČR to understand that Academy research concerns their lives. The strategy therefore made expertise more publicly legible.

This public legibility is essential in democratic societies because citizens are asked to make choices in conditions of technical and social complexity. They vote, discuss policies, choose health behaviours, respond to crises, interpret media, support or resist technologies, and form opinions about climate, migration, energy, education, and public spending. They cannot all become specialists, but they need access to reliable explanations. The Academy can contribute to civic competence by translating specialised knowledge into responsible public language. Strategy AV21 gave this translation an institutional foundation. It helped the Academy become not only a producer of knowledge, but a mediator of knowledge.

However, expertise for citizens must not become paternalistic. The Academy cannot simply speak from above and assume that citizens should accept expert conclusions without question. Public trust is built through transparency, clarity, humility, and repeated engagement. Citizens may possess local knowledge, moral concerns, practical experience, and legitimate doubts. Strategy AV21's public-interest model is strongest when it recognises this relationship as dialogic. Expert knowledge remains essential, but it enters society more effectively when it listens as well as informs. This is especially important in fields such as vaccination, climate adaptation, energy infrastructure, heritage disputes, and AI regulation.

The production of expertise also depends on the Academy's capacity for long-term research. Public institutions often need quick answers, but reliable expertise is rarely created quickly. It is built over years through data collection, laboratory work, field observation, archival research, theoretical development, evaluation, peer review, and international cooperation. Strategy AV21 made this connection clearer by showing how long-term basic research supports public usefulness. When a crisis arrives, the value of earlier investment becomes visible. A society that neglects long-term research may discover too late that it lacks the expertise it needs. The Academy's role is therefore preventive as well as responsive.

This preventive dimension is particularly important in risk governance. Many public dangers develop slowly before they become visible: climate change, biodiversity loss, antimicrobial resistance, infrastructure vulnerability, disinformation, demographic ageing, soil degradation, and social distrust. Expertise for state, society, and citizens must therefore include early warning, scenario building, monitoring, and the interpretation of weak signals. Strategy AV21's programmes were designed around contemporary challenges precisely because such challenges require anticipatory knowledge. The Academy's public value lies partly in helping society think before crisis, not only during crisis (*Renn, 2008*).

The Academy's expert role also involves the clarification of uncertainty. Policymakers and citizens often want certainty, but scientific expertise frequently provides degrees of probability, ranges of scenarios, competing models, and conditional conclusions. This is not a weakness of science; it is part of its honesty. Strategy AV21's public-interest mission required the Academy to communicate uncertainty without undermining confidence in evidence. In climate, health, AI, energy, and public policy, responsible expertise must explain what is known, what is not known, and what decisions must still be made under uncertainty. This form of communication is more difficult than simply presenting conclusions, but it is more trustworthy.

The relationship between expertise and public policy is particularly complex. Evidence-informed policy is not the same as evidence-determined policy. Research can inform policy, but policy also involves values, resources, power, law, electoral accountability, and public acceptance. Strategy AV21 allowed the Academy to contribute to policy without pretending that science alone governs society. This is important because unrealistic expectations of expertise can create disappointment when scientific advice does not produce simple solutions. The Academy's strength lies in making policy more intelligent, not in making politics disappear (*Cairney, 2016*; *Parkhurst, 2017*).

The programme Society in Motion and Public Policy embodied this role clearly. It connected behavioural sciences, economics, sociology, psychology, law, ethics, and other approaches in order to analyse a changing society and its policy needs. This was a significant step because it treated public policy itself as a research field rather than merely as an area where external

authorities apply academic results. The Academy could study how policies work, how citizens respond, how incentives operate, how inequalities are reproduced, and how institutions can be improved. Strategy AV21 therefore placed social-science expertise at the centre of the Academy's public mission.

The programme Resilient Society for 21st Century similarly showed that expertise must address the capacity of society to withstand and transform through crises. Resilience cannot be ordered administratively. It depends on trust, institutions, infrastructure, memory, communication, solidarity, health systems, education, economic capacity, and psychological adaptation. The Academy's expertise can help identify crisis potentials and conditions of effective transformation. This is expertise for the state because it informs preparedness; expertise for society because it supports institutions and communities; and expertise for citizens because it helps people understand uncertainty. Strategy AV21's value lay in connecting these levels.

The Academy's expertise also has an ethical dimension. Public-interest research must ask not only what can be done, but what should be done and under what conditions. Gene therapy, AI, surveillance, data sharing, energy choices, conservation policy, pandemic measures, and heritage interpretation all raise ethical questions. The Academy's natural and technical sciences can reveal possibilities, while social sciences and humanities can help examine consequences, values, rights, and responsibilities. Strategy AV21's interdisciplinary architecture made such ethical expertise more feasible. It allowed ethical reflection to accompany scientific and technological development rather than appear only as a later commentary.

This ethical dimension is especially important when expertise affects citizens directly. Public health measures may restrict behaviour; digital technologies may process personal data; environmental policies may affect livelihoods; energy choices may change prices and landscapes; heritage decisions may influence identity and memory. Citizens therefore have a legitimate interest in how expert knowledge is produced and used. Strategy AV21's public-interest orientation implied that expertise must be accountable, transparent, and sensitive to consequences. The Academy's independence does not free it from responsibility. It makes responsibility more serious.

Expertise also requires credibility, and credibility depends on quality control. The Academy's post-1993 reforms, institute evaluations, international peer review, and emphasis on research excellence formed the background against which Strategy AV21 could claim authority. Without scientific quality, public-interest language would be hollow. Strategy AV21 did not replace excellence with relevance; it connected them. This connection was vital because weak expertise can be more dangerous than no expertise at all. In public policy, health, energy, environment, and technology, poorly grounded advice can lead to costly or harmful decisions. The Academy's expert role therefore depends on the continued strength of its research culture.

The international dimension of expertise is also important. Contemporary problems cross borders, and national expertise is strengthened by participation in global knowledge networks. Climate science, infectious disease research, AI, energy technologies, biodiversity, public policy, and cultural heritage all require international cooperation. Strategy AV21 allowed Czech expertise to be connected with European and global agendas while remaining attentive to national needs. The Academy could translate international knowledge into Czech conditions

and present Czech research to international partners. This two-way movement is one of the functions of a modern national academy.

The European Research Area and European policy frameworks strengthened the demand for this kind of expertise. European programmes increasingly emphasised societal challenges, missions, responsible research and innovation, sustainability, digital transformation, health, security, and policy impact. The Academy's Strategy AV21 placed AV ČR in a good position to participate in these frameworks because it had already organised its public-interest agenda around comparable themes. This did not mean that the Academy merely adopted European vocabulary. It used European language to express its own institutional capacities and national responsibilities (*European Commission, 2021*).

Expertise for citizens also intersects with education. The Academy does not primarily educate through undergraduate teaching, but it shapes public knowledge through doctoral training, cooperation with universities, public lectures, exhibitions, school programmes, science festivals, media, and digital resources. Citizens need scientific literacy, historical literacy, media literacy, and civic literacy in order to navigate complex problems. Strategy AV21's thematic programmes provided content for such educational work. They helped turn Academy research into resources that could inform teachers, students, journalists, and lifelong learners. In this way, expertise became part of the broader intellectual formation of society.

The Academy's expertise is also visible in moments of public controversy. Climate change, nuclear energy, vaccination, gene technologies, AI, migration, historical memory, and European integration can all become politically polarised. In such situations, the Academy must communicate carefully. It should not pretend that scientific evidence eliminates all disagreement, but it should defend the distinction between evidence-based argument and manipulation. Strategy AV21 strengthened the Academy's ability to enter controversies with a structured public mission. Its programmes showed that the Academy was not reacting randomly to public debates, but working systematically on the problems behind them.

This capacity is especially important in the digital age, where misinformation can spread faster than expert correction. Citizens face contradictory claims, emotional narratives, manipulated images, conspiracy theories, pseudo-science, and polarised media environments. The Academy's expertise must therefore include not only knowledge of specific topics, but also communication about how knowledge is produced and evaluated. Strategy AV21's public communication and society-oriented programmes helped make this broader epistemic function visible. The Academy served citizens not only by giving answers, but by strengthening their ability to recognise better and worse forms of knowledge.

The expertise provided by the Academy also has a temporal depth that distinguishes it from consultancy. Consultants often answer a defined client problem within a short time horizon. A national academy preserves knowledge across generations. Its archives, observatories, long-term experiments, collections, data sets, scholarly editions, and theoretical traditions allow it to interpret change historically. This long memory is essential for public expertise. Without it, society risks treating every crisis as unprecedented and every policy fashion as new. Strategy AV21 made the Academy's long-term perspective more visible in relation to contemporary challenges.

The humanities are particularly important in preserving this temporal depth. Historical expertise helps policymakers and citizens understand institutional memory, previous crises, cultural identities, legal traditions, and the consequences of earlier decisions. Philology and

linguistics clarify language, communication, and interpretation. Philosophy helps examine concepts, values, and ethical limits. Archaeology and art history connect material heritage with social memory. Strategy AV21 placed these forms of expertise within the same public-interest frame as biomedical or technological knowledge. This prevented the Academy's expert role from becoming narrowly technical.

The Academy's social sciences, in turn, help translate public problems into researchable questions. They examine how citizens behave, how institutions function, how policies produce effects, how inequalities emerge, how trust is built or damaged, and how societies respond to change. This type of expertise is indispensable for state and society because many policy failures are not caused by lack of technology, but by misunderstanding human behaviour and institutional context. Strategy AV21's social programmes therefore strengthened the Academy's capacity to provide realistic advice. They showed that public-interest expertise must include knowledge of society itself.

Natural and technical sciences provide the empirical and technological foundations of many expert interventions. They make it possible to detect diseases, model climate, analyse materials, develop sensors, monitor ecosystems, improve energy systems, and understand biological mechanisms. But Strategy AV21's integrative logic ensured that such knowledge was connected with social and human dimensions. This is where the Academy's expert role became especially strong. It could offer not only facts from one field, but a structured interpretation of complex problems across fields. This is more valuable for state, society, and citizens than isolated expert fragments.

The Academy's cooperation with public administration also required institutional channels. Expert reports, advisory groups, policy consultations, public hearings, research programmes, Science4Policy initiatives, and cooperation with ministries or regional bodies all help translate research into public decision-making. Strategy AV21 provided thematic and organisational structures that made such channels easier to develop. A policymaker seeking knowledge on biodiversity, AI, public policy, energy, infectious diseases, or resilience could identify programmes and coordinators. This reduced the opacity of the Academy's internal structure and made expertise more accessible.

At the same time, institutionalised expertise must avoid the danger of routine. If expert advice becomes too close to administration, it may lose critical distance. If it remains too distant, it may lose practical influence. Strategy AV21's programme-based model allowed the Academy to stay between these extremes. It created stable channels of engagement while preserving the Academy's own research logic. This intermediate position is difficult but essential. A public academy must be close enough to society to matter and independent enough to be trusted.

Expertise for society also includes the ability to criticise public assumptions. The Academy's role is not only to provide useful information, but also to challenge false certainties. It may show that a popular solution is ineffective, that a policy rests on weak evidence, that a historical myth is misleading, that a technological promise is exaggerated, or that a risk is underestimated. Such criticism may be uncomfortable, but it is part of public interest. Strategy AV21's emphasis on top research gave the Academy the authority to perform this critical function. Public relevance does not mean pleasing the public; it means serving society's deeper need for reliable knowledge.

The citizen dimension of expertise also implies accessibility. Expert knowledge that remains inaccessible cannot fully serve the public. Accessibility does not require simplification to the

point of distortion, but it does require translation, good communication, open resources where possible, and respect for non-specialist audiences. Strategy AV21's public-facing programmes, events, and digital platforms helped the Academy move in this direction. The Academy's challenge was to make expertise usable without making it shallow. This is one of the central tasks of science communication in a democratic society.

The concept of public interest helps unify these different forms of expertise. The state needs knowledge for governance; society needs knowledge for institutional and cultural life; citizens need knowledge for orientation, judgement, and participation. Strategy AV21 placed all three within one framework. It did not define public interest only from above, as a governmental priority, nor only from below, as public demand. It treated public interest as a field in which scientific knowledge, democratic values, social needs, and long-term responsibility meet. This made the Academy's expertise both strategic and civic.

The Academy's expert role also contributed to its legitimacy before taxpayers. Public funding of research is easier to justify when citizens can see that research improves collective capacity to understand and respond to important problems. Strategy AV21 made this connection visible. It showed that the Academy's institutes do not exist only for specialist communities, although specialist research remains the foundation of their value. They also support decisions, preparedness, innovation, memory, education, culture, and public understanding. Expertise became one of the ways in which the Academy returned value to society.

This does not mean that every expert contribution has immediate measurable impact. Some forms of expertise work slowly. A historical edition may shape future scholarship and education; an environmental data set may become crucial years later; a theoretical model may later support technology; a public lecture may influence a student's career; an expert warning may prevent a poor decision that never becomes visible. Strategy AV21's public-interest orientation had to accommodate this slow impact. The Academy's value cannot be fully captured by short-term indicators. Expertise often matters most when it prevents harm, preserves capacity, or prepares society for future choices.

The expert function of Strategy AV21 also deepened the Academy's identity as a mediator between knowledge systems. It connected global science with Czech conditions, basic research with practical problems, institute expertise with public institutions, and specialised knowledge with citizen understanding. This mediating role is essential for a national academy in the 21st century. It is not enough to produce knowledge; knowledge must be interpreted, connected, communicated, and sometimes defended. Strategy AV21 provided a strategic format for this work.

Thus, Strategy AV21 strengthened the Czech Academy of Sciences as a source of expertise for the state, society, and citizens by making its knowledge more coordinated, visible, accessible, and publicly relevant. The Academy's expertise informed public policy without becoming subordinate to political command; supported society without reducing research to service provision; and addressed citizens without abandoning scientific depth. It connected energy, environment, health, security, public policy, technology, culture, memory, and resilience within a broad public-interest mission. In doing so, Strategy AV21 redefined expertise as one of the central democratic functions of the modern Academy. AV ČR became not only a producer of excellent research, but also a national institution capable of helping society understand itself, govern more intelligently, prepare for crises, and make more responsible choices about its future.

3. The Academy as a Strategic National Knowledge Institution

Strategy AV21 completed an important shift in the modern self-understanding of the Czech Academy of Sciences: it helped present the Academy not only as a network of excellent research institutes, but as a strategic national knowledge institution. This formulation is important because it captures something broader than ordinary research performance. A research institute produces knowledge in a specialised field; a grant agency distributes resources; a university combines education and research; a ministry formulates public policy. The Academy, through Strategy AV21, claimed a different and more synthetic role. It was to preserve deep scientific capacities, connect them across disciplines, translate them into public-interest programmes, communicate them to society, and make them available for the long-term needs of the Czech state, economy, culture, and citizenry. The Academy thus became visible as an institution of collective intelligence. It did not merely conduct research; it organised knowledge as a national resource. This was the culminating institutional meaning of Strategy AV21 (*Czech Academy of Sciences, 2017*).

The idea of a strategic knowledge institution differs from the older image of a classical academy. A classical academy is often associated with scholarly prestige, learned authority, disciplinary excellence, and the cultivation of science for its own sake. These qualities remained essential to AV ČR, and Strategy AV21 did not abolish them. However, the 21st century required the Academy to show how such qualities matter under conditions of technological acceleration, ecological instability, public health risks, geopolitical uncertainty, social polarisation, and cultural conflict. Strategy AV21 made it possible to connect the Academy's inherited authority with a more active public role. The Academy could remain a place of fundamental research while also becoming an institution that helps society interpret and prepare for change. Its strategic character lay precisely in this combination of depth and responsiveness.

This transformation was not a simple act of branding. It was rooted in the Academy's structural capacities. AV ČR contains institutes across natural sciences, technical sciences, life sciences, social sciences, and humanities. It maintains laboratories, archives, observatories, collections, field stations, instruments, databases, libraries, long-term research schools, expert communities, and international networks. Such capacities are not easily produced by short-term projects or policy initiatives. They accumulate over decades and require stable institutional support. Strategy AV21 gave these accumulated capacities a public architecture. It showed how the Academy's diversity could be mobilised around energy, climate, health, AI, materials, biodiversity, public policy, memory, identity, communication, and resilience. This made the Academy strategically legible.

The national dimension of this role is equally important. The Academy is not merely one research performer among many in a global system. It is a Czech public institution with responsibilities towards the Czech Republic, while remaining fully embedded in international science. Its research must contribute to global knowledge, but it also has to address the specific needs of Czech society, Czech landscapes, Czech institutions, Czech history, Czech culture, and Czech future development. Strategy AV21 expressed this dual orientation with unusual clarity. It allowed AV ČR to participate in global research on universal challenges while translating those challenges into national conditions. Climate change, AI, infectious disease, energy security, and cultural memory are global themes, but they acquire concrete meaning in

Czech forests, Czech hospitals, Czech schools, Czech public debates, Czech industries, and Czech archives.

The Academy's strategic role therefore depends on mediation. It mediates between global science and national needs, between fundamental research and practical application, between specialised expertise and public understanding, between long-term knowledge and immediate crises, between disciplinary depth and interdisciplinary cooperation. This mediating function is not secondary to research; it is one of the reasons a national academy remains necessary. No single ministry, university, company, or civic organisation can perform this function in the same way. The Academy's advantage lies in its combination of autonomy, breadth, continuity, and scientific credibility. Strategy AV21 made this combination more explicit and more operational. It gave the Academy a language for explaining why its institutional form still matters.

The strategic national knowledge institution is also an institution of preparedness. Many of the most important public challenges cannot be solved at the moment they become visible. A pandemic requires laboratories, virologists, immunologists, diagnostic methods, modelling capacities, and public communication channels that already exist. A drought requires long-term environmental monitoring, hydrological knowledge, soil research, ecological expertise, and policy analysis. An energy crisis requires knowledge of nuclear systems, renewables, storage, materials, economics, security, and public acceptance. A digital crisis requires expertise in AI, cybersecurity, language technologies, social behaviour, media, and law. Strategy AV21 showed that the Academy's public value lies not only in reacting to events, but in maintaining capacities before they are urgently needed. This is one of the strongest arguments for stable public support of academic research.

This preparedness function also explains why fundamental research remained central to Strategy AV21. Public-interest research cannot be reduced to immediate application because society often needs knowledge whose usefulness becomes clear only later. Basic discoveries in physics, chemistry, biology, mathematics, linguistics, archaeology, or philosophy may appear remote from public life at first, but they can later support technologies, therapies, policy concepts, cultural interpretation, or democratic self-understanding. Strategy AV21 did not subordinate basic research to application; it made the long-term public meaning of basic research more visible. The Academy could therefore defend scientific freedom not as a privilege of scholars, but as a condition of society's future options. This argument was especially important in a research-policy environment often dominated by measurable outputs and short funding cycles (*Polanyi, 1962; Whitley, 2000*).

The Academy's strategic role also rested on its capacity to integrate different temporal horizons. Governments often work within electoral cycles, companies within investment and market cycles, media within news cycles, and citizens within everyday pressures. The Academy can work across longer periods. It can maintain environmental series, linguistic corpora, historical editions, biological collections, astronomical observations, archaeological documentation, and theoretical schools that outlive political and economic fashions. Strategy AV21 did not replace this long duration with short-term activism. Rather, it used long-term knowledge to address contemporary challenges. This gave the Academy a temporal authority that is rare in modern public life. It could bring memory, evidence, and continuity into debates otherwise dominated by urgency.

The concept of a strategic knowledge institution also changed the relationship between the Academy and the state. The Academy was not to become an executive agency of government, but it could become a more visible source of expert knowledge for public administration and policymaking. This required a careful balance between cooperation and independence. The state needs reliable expertise, but expertise loses its value when it is politically captured. Strategy AV21 allowed the Academy to cooperate with ministries, regional administrations, public institutions, and policy actors while preserving its own scientific logic. It thus offered a democratic model of state–science relations: close enough to inform public decisions, independent enough to remain trustworthy. This was a historically significant development after the experience of state-directed science under socialism (*Jasanoff, 2004; Pielke, 2007*).

The Academy's relationship with society was broader than its relationship with the state. Strategy AV21 connected AV ČR with universities, schools, hospitals, museums, municipalities, companies, non-governmental organisations, media, and citizens. These connections helped transform the Academy's public image from a closed world of experts into a more open knowledge institution. The public-interest formula did not mean that the Academy would satisfy every immediate social demand. It meant that the Academy would organise its research in relation to problems whose consequences matter beyond the academic community. This created a more civic form of academic responsibility. The Academy remained autonomous, but its autonomy acquired a public voice.

The strategic national knowledge institution is also an institution of translation. Scientific knowledge often exists in languages, methods, and forms inaccessible to non-specialists. Strategy AV21 created thematic programmes that translated specialised research into recognisable public questions: sustainable energy, biodiversity crisis, infectious diseases, AI for science and society, society in motion, resilient society, memory in the digital age, identities in wars and crises, breakthrough technologies, and similar programme frames. These themes did not simplify science into slogans; at their best, they made the pathways between science and public life easier to understand. Translation here means institutional interpretation. The Academy explained what its knowledge is for without surrendering the complexity of how that knowledge is produced.

The same translational role operated inside the Academy. Institutes often develop their own disciplinary languages and professional cultures. Strategy AV21 translated across these internal languages by creating programme platforms where physicists, biologists, chemists, computer scientists, historians, sociologists, economists, philosophers, linguists, and legal scholars could recognise shared problems. This internal translation was a condition for external communication. The Academy could speak coherently to society only if it could also connect its own internal diversity. Strategy AV21 therefore worked simultaneously as an internal integrative mechanism and an external public narrative. It strengthened institutional unity without demanding disciplinary uniformity.

This unity was especially important because the Academy's decentralised structure is both strength and vulnerability. Its institutes are strong because they are specialised, historically grounded, and internationally connected. Yet public visibility can suffer when each institute appears separately and the Academy as a whole seems fragmented. Strategy AV21 helped overcome this problem by presenting the Academy through strategic themes rather than administrative units. The public did not need to understand the whole institutional map in order to see the Academy's relevance. It could recognise the Academy through energy, health, AI,

biodiversity, memory, society, and future technologies. This changed the Academy's public form. It became more than a sum of institutes.

The role of the Academy as a strategic knowledge institution was also visible in the innovation sphere. Strategy AV21 linked basic research with application laboratories, industrial cooperation, technological development, diagnostics, materials, energy systems, digitalisation, and future industries. This did not transform the Academy into a business incubator or applied research contractor. Rather, it positioned AV ČR as a source of advanced knowledge within the national innovation ecosystem. The Academy could support Czech competitiveness through research services, technologies, cooperation with firms, and participation in European innovation agendas. Yet its deeper contribution remained scientific: the creation of knowledge that allows future applications to exist. Strategy AV21 therefore framed innovation as a public-interest process rooted in high-quality research (*Czech Academy of Sciences, 2019; Mazzucato, 2018*).

This understanding of innovation was broader than the commercialisation of inventions. Innovation can mean new materials, but also new diagnostics, public-policy models, environmental monitoring systems, digital heritage tools, language technologies, social resilience concepts, and ethical frameworks for emerging technologies. Strategy AV21 made such a broader understanding possible because it included the full spectrum of Academy disciplines. The humanities and social sciences were not excluded from innovation; they contributed to social, cultural, communicative, and institutional innovation. This was one of the distinctive features of the Academy's strategic profile. It treated the future of society as a matter of knowledge in many forms, not only technological novelty.

The Academy's strategic role also concerned national resilience. A resilient society needs more than emergency services and infrastructure. It needs knowledge about health, communication, social trust, public policy, energy, environment, digital systems, history, identity, and risk. Strategy AV21 assembled these dimensions into programmes that could strengthen the country's capacity to understand and withstand crises. This became especially visible in the context of pandemic disruption, climate stress, war in Ukraine, energy insecurity, disinformation, and technological dependence. The Academy could not control these crises, but it could improve the intellectual resources available to society. In this sense, Strategy AV21 connected scientific research with the deeper security of democratic life.

The cultural dimension of this resilience should not be underestimated. Societies under pressure often turn to memory, identity, and history. They ask who they are, what they have endured, whom they trust, what values they defend, and how they interpret danger. The Academy's humanities institutes contribute to these questions through historical research, philosophy, philology, archaeology, literary studies, art history, and cultural analysis. Strategy AV21 placed this contribution inside the same public-interest framework as energy, medicine, and AI. This was institutionally important because it rejected a narrow, technocratic definition of national strategy. A national knowledge institution must care for meaning as well as infrastructure, for memory as well as innovation, for identity as well as technology.

The Academy's role in protecting cultural memory also has democratic significance. Authoritarian regimes often manipulate history, language, symbols, and collective identity. Democratic societies require independent scholarship capable of examining the past critically. Strategy AV21's programmes on memory, European society, materiality, and identities in crises helped present this work as part of public interest. The Academy's task was

not to produce official myths, but to preserve evidence, analyse complexity, and keep public memory open to critical interpretation. This function is strategic because societies without reliable memory are more vulnerable to propaganda and identity manipulation. The Academy therefore contributes to democratic resilience by sustaining historical and cultural knowledge.

The strategic knowledge institution also supports public reason. In a digital media environment marked by misinformation, polarisation, and rapid emotional circulation, societies need institutions that can defend standards of evidence and argument. Strategy AV21 strengthened the Academy's public voice by connecting expertise with visible programmes and communication channels. The Academy could speak on climate, health, AI, energy, public policy, biodiversity, memory, and identity not as an occasional commentator, but as an institution systematically working on these themes. This systematic character matters. It distinguishes research-based expertise from opinion and makes public communication more credible.

At the same time, the Academy's public voice must remain cautious. A strategic knowledge institution should not behave as a political actor competing for power. Its authority rests on evidence, method, peer review, disciplinary competence, and intellectual honesty. Strategy AV21 expanded the Academy's public presence, but it did not remove the need for scholarly restraint. The Academy must communicate uncertainty, explain limits, and avoid exaggerating the immediate power of science. Its strategic importance lies not in claiming omniscience, but in helping society reason better under uncertainty. This is a more modest and more durable form of authority.

The Academy's international position was also strengthened by Strategy AV21. A national academy must be national in responsibility, but international in scientific standard and cooperation. Strategy AV21's themes aligned with global and European research agendas: climate, health, AI, energy, biodiversity, resilience, heritage, and responsible innovation. This made it easier for AV ČR to participate in international networks while presenting a distinctive Czech contribution. The Academy could show that it was not isolated within national borders, but nor was it dissolved into generic global science. It occupied a productive middle position: globally connected, nationally responsible, and institutionally autonomous.

This middle position is especially important for a medium-sized European country. The Czech Republic cannot dominate global research through scale alone, but it can build strong niches, maintain excellent institutes, participate in European consortia, support specialised infrastructures, and translate international knowledge into national benefit. Strategy AV21 helped define how the Academy could contribute to this strategy. It concentrated dispersed capacities into visible themes and connected them with public needs. It also showed that national scientific capacity is not a luxury, but a condition of informed participation in the world. Countries without strong knowledge institutions become dependent on external expertise and imported technologies.

The Academy's strategic role also had implications for human capital. A national knowledge institution must cultivate future researchers, experts, technicians, communicators, and interdisciplinary leaders. Strategy AV21 created programme environments in which younger researchers could participate in cross-institute cooperation, public communication, application-oriented projects, and international networks. This did not solve all career problems, but it helped define a modern research culture. A younger scientist in AV ČR could see their work not only as a disciplinary career, but as part of a broader public-interest mission.

Such a culture matters for attracting and retaining talent. It gives scientific work social meaning without sacrificing intellectual ambition.

The relationship between Strategy AV21 and research evaluation also shaped the Academy's strategic identity. AV ČR had already developed evaluation practices to maintain quality and international credibility. Strategy AV21 added another dimension by asking how excellent research contributes to public-interest programmes. This did not mean replacing scholarly evaluation with impact rhetoric. It meant recognising that a strategic academy must assess both scientific quality and public relevance in appropriate ways. Different fields produce different kinds of value: articles, monographs, technologies, data sets, policy advice, exhibitions, diagnostics, software, methods, public communication, and expert platforms. A mature knowledge institution must understand this plurality of outputs without lowering standards.

The Academy's strategic profile therefore required plural accountability. It had to be accountable to international science through quality, to the Czech public through relevance, to the state through responsible use of public resources, to future generations through long-term capacity, and to its own scholarly communities through autonomy and integrity. Strategy AV21 helped connect these forms of accountability. It gave the Academy a framework in which excellence, service, communication, cooperation, and responsibility could be discussed together. This was one of its most important institutional achievements. It turned accountability from a defensive obligation into part of the Academy's mission.

The strategic knowledge institution also depends on infrastructure. Research infrastructures are often invisible to the public: instruments, databases, collections, laboratories, animal facilities, field stations, observatories, archives, digital platforms, and technical staff. Yet they are the material foundation of expertise. Strategy AV21 made their public meaning clearer by showing how infrastructures support programmes in energy, health, environment, AI, materials, heritage, and society. A laboratory becomes not merely a scientific workplace, but part of national preparedness. An archive becomes not merely a storage facility, but part of democratic memory. A data infrastructure becomes not merely a technical system, but part of society's capacity to understand itself.

This infrastructural view also helps explain why the Academy cannot be replaced by short-term project networks. Projects can produce important results, but they usually rely on capacities built elsewhere. A strategic academy maintains those capacities across time. Strategy AV21 did not deny the value of projects; it organised them within broader programmes and institutional continuities. This is especially important in fields where expertise must be ready before it is demanded. The Academy's long-term infrastructures and personnel make it possible for society to respond to unexpected problems. Strategy AV21 gave this argument a public form.

The Academy's relationship with citizens was also transformed by this strategic role. Citizens may not directly use most research results, but they benefit from living in a society with stronger knowledge institutions. They benefit when public policy is better informed, when health risks are studied, when environmental change is monitored, when cultural memory is preserved, when technologies are developed responsibly, and when misinformation is countered by reliable expertise. Strategy AV21 made this indirect benefit more visible. It helped citizens understand that the Academy is not remote from their lives even when its research is

highly specialised. The public-interest formula turned specialised knowledge into a civic resource.

This civic dimension also gives the Academy a moral responsibility. A strategic national knowledge institution must not serve only the strongest actors: not only ministries, large companies, elite universities, or metropolitan audiences. It should also consider the needs of regions, schools, cultural institutions, vulnerable groups, future generations, and citizens outside expert circles. Strategy AV21's public communication, thematic breadth, and openness to partners created opportunities for such a wider orientation. The Academy's public-interest mission is strongest when it recognises that knowledge serves society as a whole, not only those already capable of accessing expertise.

At the same time, the Academy must protect itself from overextension. A strategic knowledge institution cannot solve every public problem, respond to every political debate, or satisfy every demand for expertise. Strategy AV21 had to choose themes where the Academy had real capacities and where research could make a meaningful contribution. This selectivity was essential. Without it, public interest would become a vague phrase covering everything and therefore guiding nothing. The Academy's strategic maturity lies partly in knowing where it can contribute deeply and where other institutions have the primary role. Strategy is not only expansion; it is disciplined prioritisation.

The development of Strategy AV21 over more than a decade shows that the Academy learned to combine continuity with renewal. The original programmes established the public-interest orientation, while later programmes responded to emerging themes such as artificial intelligence, biodiversity, infectious diseases, identities in crises, materiality, and breakthrough technologies. This adaptability is a defining feature of a strategic institution. It keeps a stable mission while updating its agenda. Strategy AV21 therefore became not merely a programme cycle, but a mechanism of institutional learning. The Academy could revise its priorities without losing its identity.

The long-term significance of Strategy AV21 is that it gave the Academy a post-transformation narrative. After 1989 and 1993, the Academy had to justify itself through reform, autonomy, survival, restructuring, and reintegration into international science. By the 2010s and 2020s, the question had changed. The Academy no longer needed only to prove that it had escaped the socialist model. It needed to show what kind of institution it wanted to be in a democratic, European, technologically changing, and crisis-prone world. Strategy AV21 answered that question. It presented AV ČR as a public-interest academy: independent, excellent, interdisciplinary, communicative, and strategically engaged.

This narrative also connected the Academy with its earlier historical layers. The learned societies of the Czech lands had linked scholarship with culture and national self-understanding. The Czechoslovak Academy had linked science with state power, though under ideological constraint. The post-1993 Academy had linked science with autonomy and international evaluation. Strategy AV21 added a new layer: science as coordinated public-interest knowledge in a democratic society. This does not erase the previous layers. It reorganises them. The Academy remains a guardian of scholarship, a national cultural institution, a research performer, an international scientific actor, and now also a strategic knowledge institution for public challenges.

The phrase "strategic national knowledge institution" therefore captures the Academy's modern synthesis. "Strategic" points to long-term orientation, preparedness, programme

coordination, and response to major challenges. “National” points to responsibility towards Czech society, statehood, culture, regions, citizens, and future development. “Knowledge” points to the full spectrum of scientific, technical, social, and humanistic research. “Institution” points to continuity, infrastructure, autonomy, governance, and collective capacity. Strategy AV21 brought these dimensions together. It made the Academy’s mission more explicit and more persuasive in public life.

Thus, Strategy AV21 transformed the modern image of the Czech Academy of Sciences by presenting it as a strategic national knowledge institution. The Academy was no longer visible only as a federation of specialised institutes or as the successor of earlier academic traditions. It appeared as an institution capable of organising excellent research around the public interest, connecting disciplines, advising the state, serving society, communicating with citizens, cooperating with industry and universities, preserving cultural memory, supporting innovation, and preparing the country for future challenges. This transformation did not abandon the classical academy; it gave the classical academy a new civic form. AV ČR remained committed to fundamental research, scholarly autonomy, and international excellence, but Strategy AV21 showed how these values could serve the Czech Republic in the 21st century. In this sense, the strategy became one of the most important expressions of the Academy’s post-socialist maturity: not merely reformed, not merely evaluated, not merely internationally integrated, but strategically present in the public life of the nation.

Chapter Fourteen

Innovation, Technology Transfer, and the Academy's Contribution to the Czech Future

From Fundamental Research to Innovation

1. The Specific Innovation Role of a National Academy

The innovation role of a national academy cannot be understood if innovation is reduced to the language of patents, start-ups, licences, and commercial products alone. A national academy does not normally enter the innovation system as an ordinary market actor, nor does it simply imitate the behaviour of private corporate research and development units. Its deeper function is to preserve, renew, and concentrate the long-term intellectual capacity of a country, especially in fields where immediate profitability is uncertain, time horizons are long, and public value may appear before commercial value. In the Czech case, this distinction is especially important, because the Academy of Sciences of the Czech Republic inherited not only institutes, laboratories, archives, and disciplinary traditions, but also a complicated historical memory of science under different political regimes. After the institutional break with the Czechoslovak Academy of Sciences and the creation of the modern Academy in the early 1990s, the question was not merely how to keep research alive, but how to redefine the public meaning of research in a democratic, market-oriented, and internationally integrated society. The Academy's statutes define its mission broadly: it conducts research in natural, technical, social, and human sciences, advances knowledge internationally, educates researchers, disseminates and applies results for education, culture, competitiveness, and the solution of social problems (*Czech Academy of Sciences, 2006*). This formulation already indicates that innovation is not an external supplement to academic work, but one of the ways in which public research becomes institutionally meaningful. At the same time, the Academy remains a public, non-university research body funded through the Czech national budget, which means that its innovation role is inseparable from public responsibility, scientific autonomy, and the national capacity to produce independent expertise.

In this sense, the Academy's specific contribution to innovation begins before any technology is transferred and before any company is founded. It begins in the accumulation of knowledge, methods, instruments, collections, datasets, schools of thought, and highly specialised personnel. Private firms often innovate within a shorter cycle: they improve products, optimise processes, search for market niches, reduce costs, or respond to customer demand. A national academy, by contrast, works in the deeper layers of the innovation system, where future possibilities are prepared long before they become visible as marketable technologies. This is why the Academy's laboratories, institutes, and research teams should not be judged only by immediate commercial outputs. Their public value lies also in maintaining scientific fields that may later become crucial for medicine, energy, cybersecurity, environmental resilience, advanced materials, artificial intelligence, historical memory, or crisis governance. The history of Czech and Czechoslovak science shows that important applications often

emerge from research cultures that were not originally organised around direct commercialisation. The symbolic examples of Jaroslav Heyrovský's polarography and Otto Wichterle's soft contact lenses are not simply stories of individual genius; they reveal how fundamental inquiry, instrumentation, chemical imagination, and institutional continuity can unexpectedly become part of global technological change (*Míšková & Franc, 2014*; *Pokorný, 2009*). Therefore, the innovation role of the Academy is best described as infrastructural, anticipatory, and strategic rather than narrowly entrepreneurial.

The modern Academy of Sciences of the Czech Republic occupies a position between the university, the state, industry, and civil society. It is not a university, although it educates doctoral students, trains researchers, cooperates with higher education institutions, and participates in the formation of scientific careers. It is not a ministry, although its statutes explicitly state that it participates in the formation of Czech and European research and development policy (*Czech Academy of Sciences, 2006*). It is not an industrial corporation, although it cooperates with companies, develops technologies, sells licences, supports spin-offs, and increasingly professionalises technology transfer. This intermediate position gives the Academy a distinctive institutional identity. It can act as a reservoir of expertise for the state, a partner for universities, a source of high-risk knowledge for industry, and a guardian of disciplines that are indispensable for national culture but not always commercially attractive. Such a role corresponds to the broader European idea of public research organisations as institutions that connect scientific excellence with societal resilience, competitiveness, and evidence-based governance (*European Commission, 2025*). In the Czech environment, this role is sharpened by the country's post-socialist transformation, its integration into the European Research Area, and the continuing need to reduce dependence on imported technologies, external expertise, and fragmented innovation capacities.

The innovation function of the Academy is also shaped by historical discontinuity. During the socialist period, the Czechoslovak Academy of Sciences operated within a planned research system in which the relationship between science, production, and the state was formally close but politically distorted. Applied research existed, and some institutes achieved significant results, yet the system was constrained by ideological supervision, limited international exchange, bureaucratic planning, and weak market feedback. After 1989, the Academy had to pass through a difficult transformation: de-ideologisation, institutional reorganisation, budgetary pressure, evaluation, internationalisation, and the search for a new place in a pluralist research system. Innovation after socialism therefore could not simply mean "more application". It had to mean a different relationship between knowledge and society, one based on scientific credibility, institutional autonomy, legal transparency, intellectual property regimes, competition for funding, and cooperation with external partners. The Academy's post-1993 development gradually moved from survival and restructuring towards evaluation, strategic programming, and public-interest research. In this longer arc, the current emphasis on knowledge and technology transfer should be understood not as an abrupt neoliberal turn, but as a new phase in the Academy's attempt to demonstrate that long-term fundamental research is indispensable for the Czech future.

The motto of Strategy AV21, "Top research in the public interest", captures this transformation particularly well. It does not present public-interest research as a rejection of excellence, nor excellence as a self-enclosed academic value detached from society. Instead, it tries to connect the two: the Academy is expected to conduct research at an international level while orienting part of its collective capacity towards problems that exceed the boundaries of single

disciplines and single institutions. Strategy AV21 is based on coordinated research programmes and has become one of the principal formats through which the Academy presents itself as an institution capable of responding to complex societal challenges (*Czech Academy of Sciences, n.d.*). The significance of this strategy lies not only in the themes it supports, but in the institutional logic it creates. It encourages institutes to cooperate across disciplinary borders, to build links with universities, public authorities, companies, and other partners, and to articulate the public relevance of research without dissolving the autonomy of research into immediate political or commercial demand. In innovation terms, Strategy AV21 functions as a bridge between fundamental science and future application. It acknowledges that society needs not only finished technologies, but also reliable knowledge about risks, transformations, environments, health, energy, culture, and governance.

The specific innovation role of a national academy is therefore different from that of a technology agency. A technology agency normally supports applied projects, proof-of-concept schemes, and cooperation between research organisations and firms. A national academy, however, creates the knowledge base from which such projects may later emerge. It can host disciplines with no immediate market demand but high future significance, such as theoretical mathematics, fundamental physics, evolutionary biology, archaeology, linguistics, philosophy, history, or social theory. It can also sustain expensive instruments and highly specialised facilities that no individual firm or university department could maintain alone. In fields such as materials research, plasma physics, molecular biology, nanotechnology, climate science, or digital humanities, innovation depends on precisely such long-term institutional concentration. This is why the Academy's contribution should not be measured exclusively by technology transfer indicators. Patents, licences, prototypes, spin-offs, and contractual research are important, but they are only the visible part of a wider innovation ecology. Beneath them stand methods, people, tacit skills, research cultures, and the ability to ask questions that do not yet have a market.

At the same time, the Academy's innovation role cannot remain purely latent. A public research institution that insists only on long-term autonomy but cannot explain how its knowledge enters social, economic, cultural, or technological life risks political vulnerability. This was already visible in the difficult debates over the position and funding of the Academy after 1989 and again during later disputes about the value of basic research. In a democratic society, autonomy is not isolation; it is a protected condition for producing knowledge that can be trusted precisely because it is not immediately subordinated to party power, administrative convenience, or corporate profit. The Academy must therefore show how autonomy becomes usefulness without allowing usefulness to become subordination. This balance is one of the central themes of the modern AV ČR. Its statutes combine international advancement of knowledge with application of results and participation in research policy (*Czech Academy of Sciences, 2006*). The institutional message is clear: the Academy is not a secluded republic of scholars, but neither is it a contract laboratory for short-term external demand. Its task is to transform independent scientific capacity into long-term public value.

This explains why technology transfer at the Academy has increasingly become an organised institutional priority. The existence and development of the CAS Technology Transfer Centre, known as CeTTAV or CETAV, indicate that the Academy recognises the need for professional mediation between research teams and the world of intellectual property, licensing, prototypes, investors, and spin-off creation. In 2022, the Academy presented the centre as a point of guidance for institutes moving from discovery towards application, especially in areas

where researchers need legal, economic, and business support (*Czech Academy of Sciences, 2022*). The head of CeTTAV described transfer not merely as a financial mechanism, but as a way of helping researchers see their work implemented in practice and appreciated beyond the publication record. This is an important cultural shift. In older academic cultures, commercialisation could be viewed with suspicion, as if it necessarily threatened the purity of science. In contemporary public research organisations, however, the question is no longer whether knowledge should circulate beyond the laboratory, but how it can circulate without damaging scientific integrity, public ownership, and institutional fairness. The Academy's transfer structures therefore represent a new administrative and cultural layer added to its traditional research mission.

The launch of CAS Innovations, a joint-stock company fully owned by the Academy, marks a further stage in this institutionalisation of innovation. According to the Academy's announcement, the company was designed to connect scientists and investors, accelerate the path from laboratory to marketplace, introduce transparent procedures for founding technology companies, and define clear rules for bringing external capital into Academy projects (*Czech Academy of Sciences, 2026*). The announcement also stated that several CAS institutes were among the first shareholders and that the initiative would support spin-offs, start-ups, and the commercialisation of research outputs. This development is historically significant because it suggests that the Academy is moving from a decentralised and partly advisory model of transfer towards a more systematic platform for investment, incubation, and company creation. It also shows that the Academy's leadership understands innovation as a strategic matter of institutional governance, not merely as a peripheral service. However, the establishment of such a company also raises important questions that will define the next phase of Czech academic innovation: how to protect the public interest, how to distribute benefits between institutes and inventors, how to avoid premature commercial pressure on basic research, and how to maintain academic credibility while cooperating with private capital. The national academy's role here is delicate. It must help technologies leave the laboratory, but it must also ensure that public science is not reduced to an upstream subsidy for private profit.

The Academy's leadership has recently connected this transfer agenda with a broader strategic programme for institutional development. At the Academy Assembly, thirteen priorities were presented to strengthen basic and applied research, including strategic management, economy, public policy, European funding, knowledge and technology transfer, international cooperation, evaluation, scientific careers, cooperation with universities, digital transformation, research security, public communication, and Strategy AV21 (*Czech Academy of Sciences, 2026*). This list is revealing because technology transfer appears not as a solitary agenda, but as part of a wider governance architecture. Innovation depends on legislation, finance, evaluation, careers, public communication, and international partnerships. It also depends on the ability to retain excellent researchers and provide them with instruments, administrative support, and institutional confidence. If a national academy loses its best people, weakens its laboratories, or becomes trapped in bureaucratic insecurity, technology transfer will not compensate for this loss. Conversely, when excellent research is combined with professional transfer support, public policy links, and international cooperation, the Academy can become a central actor in national development. In this sense, innovation is not an isolated output category; it is the cumulative effect of a healthy research institution.

A national academy also differs from corporate R&D because it can pursue innovation in non-commercial domains. Some of the most important innovations produced by public science are conceptual, methodological, diagnostic, regulatory, educational, cultural, or institutional rather than directly technological. A new method of measuring air pollution, a historical database used in cultural policy, an epidemiological model, a legal analysis, a linguistic corpus, a biodiversity monitoring system, or an expert report for government may not become a product sold on the market. Yet each can change decisions, reduce uncertainty, preserve memory, prevent damage, or improve public governance. This is particularly relevant to AV ČR because its disciplinary range includes not only natural and technical sciences, but also social sciences and humanities. The Academy's innovation role therefore includes what might be called cognitive infrastructure: stable knowledge systems that allow society to understand itself and act more intelligently. In this respect, the humanities and social sciences are not marginal to innovation. They help define values, interpret social risks, preserve cultural memory, analyse institutions, and identify the consequences of technological change. A mature innovation system needs such knowledge just as much as it needs laboratories and prototypes.

This broader understanding of innovation is essential for the Czech case because the country's future challenges are not only industrial. They include demographic ageing, regional inequality, energy transformation, climate adaptation, public trust, disinformation, security risks, education, urban development, cultural heritage, and the changing position of small and medium-sized economies in global value chains. The Academy can contribute to these challenges precisely because it is not bound to one ministry, one industrial sector, or one electoral cycle. It can assemble interdisciplinary teams, compare long-term data, maintain continuity in expertise, and offer analyses that are not immediately reducible to political messaging. In this sense, the Academy functions as a national memory and foresight institution. It remembers what short-term policy forgets, and it investigates what markets may not yet value. The phrase "Czech future" in the title of this chapter should therefore not be read as a rhetorical flourish. It points to the Academy's role in helping Czech society imagine, test, and prepare alternative futures. Innovation, in this framework, is not only the production of new devices; it is the disciplined expansion of national possibilities.

The Academy's specific role also depends on trust. Scientific knowledge enters public decision-making only when institutions are perceived as competent, independent, and oriented towards the public good. Under authoritarian or ideologically controlled systems, academies can be mobilised to legitimise power; under market-dominated systems, they can be pressured to justify themselves by immediate economic returns. The Czech Academy's post-1989 legitimacy has rested on a different claim: that public research should be autonomous, internationally evaluated, socially useful, and institutionally accountable. This claim is not easy to sustain, because different audiences expect different things from science. Politicians may demand visible national benefits; companies may demand usable results; citizens may demand trustworthy explanations; researchers may demand freedom to pursue difficult questions. The Academy's innovation role lies in mediating these expectations without becoming captive to any single one. It must remain sufficiently close to society to be useful and sufficiently independent from society's immediate pressures to be reliable. This is a demanding institutional position, but it is precisely what distinguishes a national academy from a commercial research supplier.

The importance of this distinction becomes clearer when one considers the temporal structure of innovation. Market innovation often operates under pressure of speed: faster development, faster scaling, faster return on investment, faster product cycles. Academic innovation often begins in slowness: careful observation, method-building, replication, debate, archival work, fieldwork, instrument development, theoretical modelling, and the training of younger researchers. This slower rhythm is not inefficiency. It is the condition that makes robust knowledge possible. The Academy is especially suited to this role because its institutes can cultivate long-duration research agendas that survive beyond individual grants and political cycles. Climate science, epidemiology, archaeology, linguistics, fundamental physics, and mathematical modelling all require such continuity. When a crisis arrives, society discovers that rapid response depends on knowledge accumulated slowly before the crisis. The COVID-19 pandemic made this relationship visible across many countries, and the Academy itself presented the application of CAS research during the pandemic as an example of knowledge transfer beyond ordinary commercial metrics (*Czech Academy of Sciences, 2022*). Innovation, then, is often the delayed public return on sustained scientific patience.

The national academy's innovation role is also connected to scientific sovereignty. For a medium-sized country such as the Czech Republic, sovereignty does not mean autarky or isolation from international science. On the contrary, Czech scientific sovereignty depends on deep European and global integration. But it also requires domestic competence: the ability to understand, evaluate, adapt, and sometimes create advanced knowledge rather than merely import it. A country without strong public research institutions becomes dependent on external suppliers of technology, external interpretations of data, and external definitions of its own problems. The Academy helps prevent such dependence by sustaining expertise in fields that are strategically important even when they are not immediately profitable. This is visible in areas such as energy, materials, environmental monitoring, biomedicine, artificial intelligence, cybersecurity, and cultural heritage. It is equally visible in the social sciences, where independent analysis of inequality, public policy, political behaviour, and social change strengthens democratic self-understanding. In this sense, innovation is bound to national intellectual independence. The Academy's task is not to close Czech science within national borders, but to ensure that Czech society participates in global knowledge from a position of competence rather than dependence.

The Czech innovation system has long faced the problem of fragmentation. Public research organisations, universities, technology transfer offices, regional innovation centres, ministries, agencies, and firms do not automatically form a coherent ecosystem. The European Commission's Policy Support Facility review of the Czech knowledge transfer system identified the need to reform technology transfer and knowledge valorisation practices, improve the institutional framework for technology transfer offices, and align them better with the needs of the Czech research, development, and innovation environment (*European Commission, 2025*). This diagnosis is important for understanding the Academy's current direction. CAS Innovations, CeTTAV, Strategy AV21, and application-development programmes can be seen as Academy-level responses to a wider national problem: how to move from dispersed excellence and isolated transfer initiatives towards more coherent pathways from knowledge to use. The Academy alone cannot solve the structural weaknesses of the Czech innovation system. Yet because it is the largest non-university research institution in the country and has institutes across many disciplines, it can act as one of the system's stabilising platforms. Its

innovation role is therefore both internal and external: it must organise transfer within its own institutes and help improve the wider national architecture of knowledge circulation.

The Academy's role is further complicated by the dual expectation that it should support both basic and applied research. In public debates, these categories are often treated as opposites, as if basic research were abstract and applied research practical. In reality, they are historically interdependent. Many applied breakthroughs depend on discoveries that were originally basic, while applied problems often generate new theoretical questions. The Academy's specific value lies in being able to hold these two dimensions together. It can protect curiosity-driven research while also building mechanisms that allow promising results to move towards application. This is why the Academy's recent priorities refer to both basic and applied research, rather than presenting innovation as a replacement for scientific excellence. The distinction matters politically: if innovation policy weakens basic research, it undermines the very source of future innovation. If basic research refuses all pathways to application, it becomes vulnerable to the charge of public irrelevance. The Academy must therefore defend a dynamic continuum rather than a rigid hierarchy.

This continuum is also visible in the way the Academy cooperates with industry. Industrial partners often seek solutions, expertise, measurement, prototypes, analyses, or access to specialised equipment. Academy institutes can provide these, but their strongest contribution often lies not in routine service work, but in the capacity to address problems that exceed ordinary corporate laboratories. When cooperation is well designed, industry gains access to high-level knowledge, while researchers gain insight into practical constraints, technological needs, and possible applications of their work. However, the Academy must avoid becoming dependent on low-value contractual tasks that consume scientific capacity without advancing research. The innovation role of a national academy is not to replace private R&D, but to complement it where public research has comparative advantage. This includes high-risk inquiry, long-term exploration, interdisciplinary methods, sophisticated instrumentation, and independent validation. The Academy's cooperation with firms is therefore most valuable when it transforms both sides: companies become more knowledge-intensive, and research teams become more aware of the technological and social environments in which their discoveries may matter.

The same logic applies to cooperation with ministries, regions, and municipalities. Public authorities need expert knowledge in areas such as environmental protection, transport, education, social policy, public health, energy, regional development, and cultural heritage. The Academy can offer this knowledge because its institutes often maintain long-term datasets, historical expertise, modelling capacity, and specialist communities that are not available inside administrative bodies. Unlike private consultancy, academic expertise is ideally grounded in peer-reviewed knowledge, methodological transparency, and institutional independence. This does not mean that academy experts are infallible or politically neutral in a simplistic sense. It means that their authority derives from professional standards rather than from immediate political advantage. For a democratic state, such expertise is a form of institutional capital. It allows public decision-making to be more informed, and it helps society distinguish between knowledge, opinion, lobbying, and propaganda. In this respect, the Academy's innovation role includes the innovation of governance itself: better concepts, better evidence, better risk assessment, and better long-term planning.

The specificity of the Academy's innovation role also comes from its disciplinary plurality. A technical university may specialise in engineering education and applied technological development; a ministry may focus on sectoral policy; a corporation may focus on market value; a regional centre may focus on local entrepreneurship. The Academy combines institutes in physics, chemistry, biology, medicine, mathematics, computer science, earth sciences, humanities, and social sciences. This breadth allows it to address problems that cannot be solved inside one disciplinary language. Climate adaptation, for example, requires atmospheric science, hydrology, ecology, economics, public policy, sociology, urban planning, and communication. Artificial intelligence requires mathematics, computer science, ethics, law, linguistics, psychology, labour-market analysis, and security studies. Biotechnology requires molecular biology, medicine, intellectual property, public trust, regulation, and bioethics. Cultural memory requires archaeology, history, philology, digital technologies, conservation science, and public education. The Academy's innovation role therefore emerges from its capacity to create interdisciplinary combinations that are difficult to generate in narrower institutions. This is one of the reasons why Strategy AV21 is not a secondary programme but a revealing expression of the Academy's institutional logic.

A national academy also contributes to innovation by forming scientific elites. Innovation systems do not consist only of organisations and funding streams; they depend on people capable of moving between fundamental research, technological development, public communication, and institutional leadership. The Academy trains such people through doctoral supervision, postdoctoral careers, research teams, international projects, and collaboration with universities. It also provides a professional environment in which younger researchers can learn how to work with complex instruments, international standards, peer review, grant competition, intellectual property, and public responsibility. This human-capital dimension is often underestimated because it is harder to measure than patents or spin-offs. Yet it may be the Academy's most durable contribution. Researchers trained in Academy institutes may later move to universities, companies, ministries, international organisations, or start-ups, carrying with them methods, standards, and networks. In this way, the Academy diffuses innovation through careers as well as through technologies. It produces not only results, but also people who know how to produce reliable results.

The Academy's innovation role is therefore inseparable from evaluation and quality control. If public research is to support innovation, it must first be excellent research. Weak science does not become useful merely because it is labelled applied. The Academy's modern development has included repeated efforts to evaluate institutes, internationalise standards, and distinguish genuine excellence from institutional inertia. Recent Academy statements have connected future priorities with evaluation, excellent research, scientific careers, and applicability of results (*Czech Academy of Sciences, 2026*). This combination is important because innovation policy can easily become performative: institutions may count outputs without asking whether they are scientifically strong or socially meaningful. A national academy must resist such superficiality. It must cultivate evaluation systems that recognise diverse forms of value: frontier publications, instruments, datasets, patents, expert reports, public engagement, cultural work, and long-term disciplinary stewardship. The challenge is to avoid both extremes: a narrow bibliometric model that ignores application, and a narrow commercial model that ignores scientific depth. The Academy's institutional maturity will be measured by its ability to evaluate innovation without simplifying science.

The Czech Academy's current movement towards more active transfer should also be read against the broader European shift from "technology transfer" to "knowledge valorisation". The older model often imagined a linear path from laboratory discovery to patent, licence, company, and market. Contemporary European policy increasingly emphasises wider circulation of knowledge: co-creation, open science, public engagement, standards, social innovation, policy advice, and responsible innovation. The Academy's own profile fits this broader model better than a purely linear commercialisation scheme. Its institutes generate technologies, but they also generate expertise, methods, databases, cultural interpretations, and public evidence. The establishment of transfer structures is therefore necessary but not sufficient. The Academy also needs channels for policy transfer, educational transfer, cultural transfer, and societal learning. Strategy AV21 partly fulfils this function by framing research around public-interest challenges rather than only around intellectual property. The future of the Academy's innovation role will depend on whether it can integrate commercial transfer with this richer understanding of public value.

The institutional identity of AV ČR therefore contains a productive tension. On the one hand, it is a guardian of long-term academic autonomy and disciplinary continuity. On the other hand, it is increasingly expected to become a visible actor in the national innovation ecosystem. This tension should not be treated as a weakness. It is precisely the tension that makes a national academy useful. If it were only autonomous, it might become socially isolated; if it were only application-oriented, it might lose the depth that makes its applications valuable. The Academy's task is to inhabit the space between these poles with intelligence and institutional discipline. It must preserve the freedom to ask questions that no client has commissioned, while also building the competence to move discoveries into public use when the opportunity arises. It must speak both the language of science and the language of society without allowing either to corrupt the other. This is why the Academy's innovation role is not an administrative add-on, but a central expression of its modern public mission.

The specific Czech dimension of this role lies in the country's historical experience with science as both a national-cultural project and a state-organised institution. From the learned societies and museums of the national revival to the Czechoslovak Academy, from socialist centralisation to post-1989 democratic reform, Czech science has repeatedly been asked to define its relation to the nation, the state, and the wider world. The modern AV ČR inherits this layered history. Its innovation role therefore cannot be reduced to the vocabulary of competitiveness alone, even though competitiveness is explicitly included in its statutory mission (*Czech Academy of Sciences, 2006*). It also concerns cultural continuity, democratic expertise, scientific freedom, and the capacity of a small European country to participate in global knowledge production. In this respect, innovation becomes a historical category. It is not merely the new replacing the old, but the ability of an institution to transform inherited capacities into future-oriented public value. The Academy's laboratories, archives, institutes, and intellectual traditions are not relics of the past; they are resources for imagining and building the future.

Thus, the specific innovation role of a national academy such as AV ČR lies in its ability to connect long-term fundamental research with public usefulness without collapsing science into short-term commercial or political demand. Its contribution begins in the maintenance of deep disciplinary competence, specialised infrastructures, international standards, and scientific elites, and only later becomes visible in licences, spin-offs, prototypes, policy advice, public expertise, and cultural knowledge. The Academy's recent development — Strategy

AV21, professional technology transfer, application-development programmes, and CAS Innovations — shows a clear movement towards a more active and organised innovation function. Yet the Academy's greatest value remains its capacity to produce knowledge that society cannot easily commission because it does not yet know that it will need it. For the Czech future, this means that AV ČR is not simply one actor among others in the innovation system. It is a long-term public institution that helps the country preserve intellectual sovereignty, prepare for technological change, and transform scientific autonomy into responsible national development.

2. Long-Term Research as the Basis of Future Technologies

Long-term research is the quiet prehistory of future technologies. It rarely looks dramatic at the moment when it is being done, because it often consists of careful measurement, theoretical clarification, patient experimentation, repeated failure, and the gradual formation of specialist communities. Yet many technologies that later appear revolutionary are not born suddenly in the marketplace; they are assembled over decades from concepts, instruments, materials, algorithms, data, and human skills produced in research environments that were not initially organised around immediate commercial use. This is why a national academy is especially important for an innovation system. It gives a country a place where questions can be pursued before they are profitable, before they are politically fashionable, and sometimes even before their practical meaning can be fully understood. In the Czech case, this function belongs at the centre of the institutional history of AV ČR, because the Academy's modern mission explicitly combines the advancement of knowledge with service to Czech society, national culture, education, competitiveness, and the solution of contemporary problems (*Czech Academy of Sciences, 2006*). The deeper point is that these aims do not contradict one another. Knowledge becomes socially useful precisely because, for a time, it is allowed to develop according to the internal standards of science.

The relation between long-term research and technology has often been described through the language of "basic" and "applied" science, but that distinction can be misleading if it is treated too mechanically. The classical post-war argument, expressed most famously by Vannevar Bush, presented basic research as a source of future practical advances, a reservoir from which medicine, defence, industry, and public welfare would later draw (*Bush, 1945*). Later scholarship complicated this linear model by showing that science and technology interact in more circular ways: application can stimulate theory, instruments can transform concepts, and practical problems can open new fields of fundamental inquiry (*Stokes, 1997*; *Edgerton, 2006*). Yet the correction of the linear model should not lead to the opposite error, namely the belief that all research must be immediately application-driven. The most productive innovation systems usually contain both curiosity-driven research and mission-oriented programmes, both disciplinary depth and interdisciplinary problem-solving, both slow accumulation and rapid translation. The Academy's specific role lies in holding these time horizons together. It is not only an institution that produces usable results; it is an institution that preserves the conditions under which unexpected future usability becomes possible.

A future technology begins as an option before it becomes an application. A new mathematical method, a new spectroscopic technique, a new understanding of protein structure, a new material, a new archaeological database, or a new model of climate risk may remain for years within a specialised scientific environment. During that time, it may not attract investors, it may

not appear in policy slogans, and it may not yet have a clear industrial partner. Nevertheless, it enlarges the field of possible action. When circumstances change — when a disease appears, an energy system becomes unstable, a manufacturing process reaches its limits, or a society faces an environmental crisis — such accumulated knowledge can suddenly become indispensable. The innovation value of long-term research is therefore partly hidden until the moment when it becomes necessary. A national academy protects this hidden value. It does so by maintaining laboratories, collections, archives, observatories, experimental platforms, computational capacity, disciplinary schools, and research careers across periods when public attention moves elsewhere.

This is particularly important for a medium-sized country such as the Czech Republic. Large states can sometimes rely on the scale of their universities, defence laboratories, private corporations, and federal research agencies to preserve scientific breadth. Smaller and medium-sized countries must be more deliberate. They need institutions that prevent strategic knowledge from becoming too fragmented, too dependent on imported expertise, or too vulnerable to short-term political budgeting. AV ČR performs this function by sustaining research across the natural, technical, medical, social, and human sciences. Its mission statement emphasises highly specialised and interdisciplinary research, international standards, Czech social needs, and national culture (*Czech Academy of Sciences, n.d.*). This is not merely institutional rhetoric. It reflects a structural necessity: Czech future technologies will not arise only from entrepreneurial energy, but from a national capacity to understand advanced science, operate complex infrastructures, train researchers, and participate in international knowledge networks from a position of competence.

The historical experience of Czech and Czechoslovak science confirms this point. The strongest technological legacies did not emerge only from formally applied programmes. They often arose from a dense interaction between theoretical curiosity, laboratory craftsmanship, disciplinary tradition, and institutional support. Jaroslav Heyrovský's polarography and Otto Wichterle's work on soft contact lenses became emblematic because they showed that Czech science could generate discoveries with international technological consequences, even when the original research context was not reducible to commercial product development (*Míšková & Franc, 2014*; *Pokorný, 2009*). These examples matter not because history should be used nostalgically, but because they reveal the anatomy of future-oriented research. The decisive factors were not only ideas, but also instruments, chemical cultures, experimental habits, institutional continuity, and the ability to transform a scientific problem into a usable method or material. The lesson for AV ČR is clear: future technologies are rarely invented by isolated acts of inspiration. They are prepared by research cultures that keep producing competence before the market knows how to value it.

After 1989, this relationship between long-term research and future application acquired a new institutional meaning. The Academy had to defend its place in a democratic and market-oriented system where public spending, evaluation, international competition, and economic usefulness were all increasingly scrutinised. In such an environment, long-term research could easily be caricatured as expensive, slow, or insufficiently responsive to society. Yet the transformation period also showed that a country which weakens its public research base loses future options. The closure, downsizing, or fragmentation of research institutes may create short-term savings, but it can destroy tacit knowledge, experimental schools, and technical capacities that cannot be rebuilt quickly. This is why the survival and later modernisation of AV ČR were not merely administrative achievements. They preserved a

national research substrate from which later innovation, technology transfer, and public-interest programmes could grow. The Academy's current innovation agenda stands on the institutional endurance created during those difficult post-socialist decades.

Long-term research also matters because technologies increasingly arise from convergence between fields. Artificial intelligence depends on mathematics, statistics, computer science, linguistics, cognitive science, ethics, law, and domain-specific data. Biotechnology depends on molecular biology, genomics, bioinformatics, imaging, chemistry, medicine, regulation, and public trust. Climate technologies depend on atmospheric science, ecology, hydrology, materials, energy systems, economics, regional policy, and social behaviour. Advanced materials depend on physics, chemistry, nanotechnology, modelling, microscopy, and industrial engineering. Cultural memory increasingly depends on history, archaeology, philology, conservation science, digital platforms, imaging, and data curation. None of these combinations can be built overnight. They require institutions that preserve disciplinary depth while making interdisciplinary contact possible. This is precisely the terrain on which AV ČR is strongest: not as a single-purpose innovation factory, but as a multi-institute environment in which future technological directions can be assembled from older scientific strengths.

Strategy AV21 represents one of the most visible attempts to translate this long-term capacity into a public-interest format. Its official presentation describes coordinated research programmes focused on contemporary social challenges and the practical application of research results in economically and socially important areas (*Czech Academy of Sciences, n.d.*). The language of Strategy AV21 is significant because it does not abandon fundamental research; rather, it asks how high-level research can be organised around problems that require time, interdisciplinarity, and cooperation outside the Academy. In this sense, the strategy is not simply an application programme. It is a mechanism for turning accumulated research competence into anticipatory capacity. It allows the Academy to say: we do not merely respond to the present; we help formulate the problems of the future. In innovation terms, Strategy AV21 therefore occupies the space between basic research and mission-oriented research. It gives long-term inquiry a public vocabulary without reducing it to short-term utility.

The Czech national system of large research infrastructures also shows why future technologies depend on long temporal investment. The Czech Roadmap of Large Research Infrastructures presents these infrastructures as strategic national capacities and places them in relation to the European research infrastructure landscape. The 2023–2026 update includes forty-three large research infrastructures across six broad fields: physical sciences and engineering, energy, environmental sciences, health and food, social sciences and humanities, and e-infrastructures or digital research infrastructures (*Ministry of Education, Youth and Sports, 2024*). These infrastructures are not ordinary laboratory equipment. They are shared platforms, often open to users from different institutions and countries, where experimental, computational, observational, or data-intensive research can be performed at a level impossible for isolated research groups. Their importance lies not only in what they currently measure or produce, but in the future communities and methods they make possible. A country that invests in such infrastructures invests in the technological questions that have not yet fully arrived.

Infrastructures such as ELI Beamlines, CzechNanoLab, ELIXIR CZ, and CzeCOS illustrate different dimensions of this long-term logic. ELI Beamlines belongs to the European Extreme

Light Infrastructure and supports frontier laser-based research with implications for physics, materials science, biomedical research, and laboratory astrophysics (*ELI Beamlines, n.d.*). CzechNanoLab provides open access to tools and expertise in nanoscience and nanotechnology, a field where future advances in electronics, materials, sensors, energy, and biomedicine depend on the ability to fabricate and analyse structures at extremely small scales (*CzechNanoLab, n.d.*). ELIXIR CZ offers data resources, specialised databases, tools, and e-infrastructure services for life-science researchers, reflecting the fact that future biology and medicine will be inseparable from data organisation and computational analysis (*ELIXIR CZ, n.d.*). CzeCOS provides a platform for interdisciplinary research on global change and its impacts on ecosystems, linking long-term environmental observation with adaptation and mitigation knowledge (*CzeCOS, n.d.*). None of these capacities can be understood as a simple "product pipeline". They are conditions for many possible future pipelines.

The same point applies to data infrastructures, which are increasingly central to future technologies. In older models of innovation, instruments and laboratories were often imagined as physical spaces filled with machines, chemicals, microscopes, or reactors. Today, data, algorithms, repositories, standards, metadata, and interoperability protocols are equally important. A future medical discovery may depend on biological databases; a future climate policy may depend on long-term environmental series; a future cultural heritage tool may depend on digitised archives and linguistic corpora; a future AI system may depend on carefully curated national-language datasets. AV ČR's long-term contribution is therefore not limited to visible inventions. It includes the creation of reliable epistemic environments in which data can be gathered, preserved, interpreted, and reused. This is why e-infrastructures in the Czech roadmap should be seen as part of scientific sovereignty rather than as a technical support function. Without data capacity, even excellent researchers become dependent on external platforms and external standards.

Long-term research also produces what might be called technological memory. This memory is not a passive archive of past results; it is a living capacity to know why certain methods work, why others failed, and how instruments, materials, and models have evolved. In laboratories, much of this memory is tacit. It is carried by technicians, senior researchers, engineers, software developers, archivists, curators, and experimental teams who know how to make complex systems function. When institutions are stable, this memory is transmitted between generations. When institutions are repeatedly disrupted, it is lost. The post-socialist transformation of Czech science was therefore not only a matter of legal reform and budgetary reallocation. It was also a struggle to preserve scientific memory while removing the political distortions of the socialist system. AV ČR's present capacity for innovation rests partly on the fact that enough of this memory survived and was reconnected to international science.

The technological future also depends on negative knowledge: knowledge of limits, risks, failures, and unintended consequences. Commercial R&D is often under pressure to produce a positive result, a deliverable, a marketable output, or a competitive advantage. Long-term academic research can investigate why a path is unsafe, why a material degrades, why an ecological intervention fails, why a model is unreliable, or why a social technology creates new inequalities. This form of knowledge may not look innovative in a narrow commercial sense, but it prevents costly mistakes and makes future technologies more robust. In climate research, for example, long-term observation helps distinguish structural trends from short-term fluctuation. In biomedicine, fundamental research helps prevent premature therapeutic claims. In artificial intelligence, theoretical and social analysis can identify risks in data, bias,

governance, and responsibility. A national academy contributes to innovation not only by accelerating technological change, but by making it more intelligent.

This is why the Academy's humanities and social sciences also belong to the foundation of future technologies. Technologies do not enter empty space; they enter societies with languages, institutions, inequalities, legal systems, memories, and cultural expectations. The future of AI in Czech society, for example, cannot be understood only through algorithms and computing power. It requires analysis of education, labour markets, public administration, ethics, media, language technologies, security, and democratic trust. Biotechnology requires not only molecular research, but also regulation, bioethics, public communication, and historical awareness of medical authority. Climate adaptation requires not only environmental modelling, but also understanding of municipalities, property relations, regional identities, public finance, and citizen behaviour. Cultural memory in the digital age requires not only scanning technologies, but also interpretation, classification, context, and responsibility towards historical evidence. AV ČR's disciplinary breadth makes it one of the few Czech institutions able to connect these layers over long periods.

The European context strengthens this argument. ESFRI describes research infrastructures as strategic instruments for scientific integration in Europe and for strengthening Europe's international outreach, while the Czech roadmap explicitly places national infrastructures in this wider European landscape (*ESFRI, n.d.*; *Ministry of Education, Youth and Sports, 2024*). For Czech science, this means that long-term research is not national isolation. It is the precondition for meaningful participation in European science. A country can join European infrastructures formally, but without domestic expertise it cannot fully use them. It can import technologies, but without its own research culture it cannot evaluate, adapt, or improve them. AV ČR's long-term research therefore supports Czech participation in the European Research Area not as a peripheral consumer, but as a contributor. This European embeddedness is one of the major differences between the contemporary Academy and the more constrained international position of science under state socialism.

The economic meaning of long-term research becomes clearer when placed against current Czech innovation challenges. The European Innovation Scoreboard 2025 notes that Czechia has a strong industrial base and performs well in medium- and high-tech product exports, but it also points to weaknesses in intellectual asset management, knowledge-intensive services, and some forms of public support for R&D (*European Commission, 2025*). This creates a specific strategic problem. Czech industry can be technologically capable, but without stronger knowledge valorisation and deeper public-private research linkages, the country may remain more dependent on manufacturing strength than on original knowledge-based value creation. AV ČR cannot solve this problem alone, but it can help shift the balance by supplying the deeper research base from which higher-value technologies, spin-offs, expert services, and advanced industrial cooperation can emerge. Its role is especially important because the country's innovation challenge is not only to produce more products, but to produce more original knowledge that can be transformed into products, policies, and platforms. Long-term research is therefore an economic resource, even when its economic value appears only after many years.

The European Commission's Policy Support Facility review of knowledge transfer in Czechia similarly emphasised fragmentation in the research and innovation system and the need for clearer responsibilities and better alignment of knowledge transfer policies (*European*

Commission, 2025). This diagnosis indirectly supports the case for a strong national academy. Fragmented systems require institutions capable of continuity, coordination, and high trust. AV ČR's institutes cannot replace ministries, universities, firms, or regional innovation centres, but they can provide stable scientific competence inside an otherwise dispersed ecosystem. The review also noted the broader interpretation of knowledge transfer visible in Czech policy discussions, including open science and popularisation, rather than only commercial technology transfer (*European Commission, 2025*). This broader concept fits the Academy's long-term role very well. It means that knowledge produced over decades can become valuable through many channels: licensing, public policy, education, expert reports, datasets, standards, crisis response, cultural interpretation, and public communication.

This broader view helps explain why technology transfer offices and innovation companies should be seen as the visible end of a much longer process. CeTTAV, CAS Innovations, and programmes supporting commercialisation are necessary because scientific results do not automatically move into practice. They require intellectual property strategy, legal protection, proof-of-concept support, business development, investor communication, and sometimes the creation of spin-off companies. The Academy has recently strengthened this layer: CAS Innovations was presented as a mechanism to connect scientists and investors and accelerate the path from laboratory to marketplace, while the PRAK programme supports research teams seeking licensing agreements, spin-offs, or positive social impact (*Czech Academy of Sciences, 2026*; *Czech Academy of Sciences Transfer Centre, 2025*). Yet these mechanisms do not create research ex nihilo. They harvest, select, protect, and develop outputs that long-term research has made possible. The danger would be to confuse the transfer mechanism with the source of innovation itself. The source remains the accumulated scientific capacity of the institutes.

A useful way to understand this relationship is to distinguish between discovery time, maturation time, and transfer time. Discovery time belongs to fundamental inquiry: it asks what is true, what is possible, what mechanisms exist, and what methods can reveal them. Maturation time belongs to the slow strengthening of a result: replication, scaling, instrumentation, comparison, data accumulation, safety assessment, and interdisciplinary interpretation. Transfer time belongs to the movement from research environment to application environment: patents, licences, prototypes, spin-offs, public policy use, or professional practice. Innovation policy often sees only the third phase because it is administratively visible. A national academy must protect all three. If it focuses only on discovery, useful results may remain locked inside laboratories. If it focuses only on transfer, it will eventually exhaust the reservoir of discoveries. If it supports maturation, it can turn scientific insight into a credible future technology without sacrificing scientific standards.

This logic is especially relevant for AI, biotechnology, climate research, materials science, and cultural memory, which will be discussed more fully in the later section on emerging fields and strategic research directions. Each of these areas depends on long-term accumulation. AI needs not only computing power, but also mathematical competence, language resources, domain datasets, ethical frameworks, and secure digital infrastructure. Biotechnology needs biological data, laboratory platforms, imaging, bioinformatics, clinical cooperation, and regulatory understanding. Climate research needs long-term observations, ecosystem monitoring, modelling, and communication with public authorities. Materials science needs laboratories that can fabricate, characterise, and test materials across scales. Cultural memory needs archives, digitisation, conservation science, historical interpretation, and tools

for public access. In each case, the future technology is not a single invention; it is a system of knowledge, infrastructure, people, standards, and institutions.

The Academy's long-term research role also has a democratic dimension. Public societies need institutions that can think beyond electoral cycles and market cycles. Climate adaptation, demographic change, energy transformation, digital security, public health, and cultural memory cannot be responsibly managed through short-term reaction alone. They require continuity of observation, independence of judgement, and the ability to compare current choices with historical experience and future scenarios. AV ČR can contribute to this democratic capacity because it is not built around one political programme or one corporate strategy. Its public funding creates obligations, but also gives it a degree of independence from immediate demand. In a well-functioning research system, this independence should not be viewed as privilege. It is a social mechanism for protecting difficult knowledge until society is ready to use it.

There is, however, a permanent institutional risk. Long-term research can become self-protective if it loses contact with external problems; innovation policy can become superficial if it measures only immediate outputs. The Academy must therefore avoid both academic isolation and managerial impatience. It needs evaluation systems that reward genuine excellence, interdisciplinary cooperation, infrastructure stewardship, public relevance, and responsible transfer. It also needs career structures that allow researchers to work on difficult long-term problems without being punished for not producing instant commercial results. This is particularly important for early-career researchers, whose work often depends on short grants and precarious project cycles. If the Academy wants to remain the basis of future Czech technologies, it must protect not only instruments and buildings, but also the time of researchers. Scientific time is itself an infrastructure.

The political economy of long-term research is also delicate. Governments often support science rhetorically but demand quick indicators when budgets are strained. Industry often praises innovation but may underinvest in risky pre-competitive knowledge. Citizens value expert knowledge in crises but may not see why it must be funded before the crisis. This creates a recurrent legitimacy problem for academies. AV ČR's answer must be not only communication, but demonstration through credible examples: crisis expertise, climate services, biomedical methods, materials innovations, digital resources, cultural heritage tools, policy analysis, and spin-offs where appropriate. The point is not to turn every institute into an innovation office. The point is to show that the Academy's long-term research is a national reserve of competence. In a century of technological volatility, such reserves may be as important as financial or military reserves.

The Czech future will depend heavily on whether the country can move from being a successful industrial and engineering economy to being a deeper knowledge economy. This does not mean abandoning manufacturing or applied engineering; it means strengthening the scientific foundations that allow industry, public policy, and culture to move upwards in complexity. Long-term research is the source of this upward movement. It produces the advanced methods that industry later uses, the datasets that ministries later need, the models that municipalities later consult, the materials that companies later commercialise, the biological understanding that medicine later applies, and the cultural interpretations that society later uses to understand itself. AV ČR's contribution is therefore not exhausted by any single technological

success. It is systemic. It helps sustain a national environment in which future technologies can be imagined, tested, criticised, matured, and responsibly applied.

Thus, long-term research is not the opposite of innovation, but its deepest temporal foundation. The Academy's laboratories, infrastructures, archives, datasets, scientific schools, and interdisciplinary programmes prepare future technologies by preserving knowledge before it becomes useful, maturing discoveries before they become transferable, and maintaining expertise before crises make it visibly necessary. For AV ČR, this role is historically and strategically decisive: it connects the Academy's inherited mission of advancing knowledge with the contemporary demand for technological sovereignty, social resilience, and public value. The future technologies of the Czech Republic will not emerge only from start-ups, industrial contracts, or short-term programmes, although all of these have their place. They will emerge from the long continuity of research cultures able to ask difficult questions, operate complex instruments, educate new scientific elites, and connect Czech society to the most demanding currents of European and global science. In this sense, the Academy is not merely a participant in innovation. It is one of the institutions that makes a Czech technological future thinkable.

3. The Difference Between Academic Innovation and Commercial R&D
